

Standard Specification for Establishing and Monitoring Structural Capacities of Prefabricated Wood I-Joists¹

This standard is issued under the fixed designation D5055; the number immediately following the designation indicates the year of original adoption or, in the case of revision, the year of last revision. A number in parentheses indicates the year of last reapproval. A superscript epsilon (ϵ) indicates an editorial change since the last revision or reapproval.

1. Scope

1.1 *General*—This specification gives procedures for establishing, monitoring, and reevaluating structural capacities of prefabricated wood I-joists. Capacities considered are shear, reaction, moment, and stiffness. Procedures for establishing common details are given and certain design considerations specific to wood I-joists are itemized.

1.2 *Contents of the Standard*—An index and brief description of the main features of this specification are given in [X2.1.1](#).

1.3 *Development of the Standard*—The development and intent of this specification is discussed in [Appendix X2](#).

1.4 The values stated in inch-pound units are to be regarded as standard. The values given in parentheses are mathematical conversions to SI units that are provided for information only and are not considered standard.

1.5 *This standard does not purport to address all of the safety concerns, if any, associated with its use. It is the responsibility of the user of this standard to establish appropriate safety and health practices and determine the applicability of regulatory limitations prior to use.* A specific precautionary statement is given in [6.1.1.5](#).

3. Terminology

3.1 Definitions:

3.1.1 *prefabricated wood I-joint*—a structural member manufactured using sawn or structural composite lumber flanges and structural panel webs, bonded together with exterior exposure adhesives, forming an “I” cross-sectional shape. These members are primarily used as joists in floor and roof construction.

3.2 Definitions of Terms Specific to This Standard:

3.2.1 *capacity (or structural capacity)*—the numeric result of certain calculations specified in this specification.

3.2.2 *design value*—the numeric value claimed by the manufacturer as appropriate for use in structural analysis.

NOTE 1—A brief discussion of this issue is found in [X2.9](#).

3.2.3 *structural composite lumber*—a composite of wood elements (for example, wood strands, strips, veneer sheets, or a combination thereof), bonded with an exterior grade adhesive and intended for structural use in dry service conditions.

4. Design Considerations

4.1 Design Value Adjustments:

4.1.1 *Duration of Load*—With the exception of reaction design values limited by compression perpendicular to grain, prefabricated wood I-joists shall be designed using the strength adjustment for load duration used in sawn lumber. This adjustment is determined in accordance with the section on Duration of Load Under Modification of Allowable Properties for Design Use in Practice [D245](#).

4.1.2 *Repetitive Members*—The repetitive member factor for prefabricated I-joists shall be taken as 1.0.

NOTE 2—Committee D07 chose to reduce the repetitive member factor to unity primarily for purposes of design simplicity. A discussion of this decision is given in [Appendix X2](#).

4.1.3 *Treatments*—Some pressure treatments affect material strength and the quality of prefabricated wood I-joists. Treated I-joists shall not be used without evaluation of such effects.

⁶ Available from National Lumber Grades Authority (NLGA), 302–960 Quayside Drive, New Westminster, BC V3M 6G2, Canada, <http://www.nlga.org>.

⁷ Available from International Organization for Standardization (ISO), 1, ch. de la Voie-Creuse, CP 56, CH-1211 Geneva 20, Switzerland, <http://www.iso.org>.

4.1.4 *Environment*—The capacities developed in this specification are applicable to joists used under dry conditions such as in most covered structures. Appropriate adjustments for uses in other environments shall be made.

4.2 Shear Design:

4.2.1 Neglecting loads within a distance from the support equal to the depth of the member shall not be permitted.

4.2.2 Adjustments to the shear design value near the support or at locations of continuity or where reinforcements are provided must be substantiated by independent testing to the general intended criteria for shear capacity herein.

5. Materials

5.1 *General*—The following I-joint components meet the definition of a biobased product in accordance with 3.3.1 of Guide [D7480](#):

5.1.1 Lumber flange materials complying with USDOC PS-20, CSA O141, NLGA SPS-1, or NLGA SPS-4.

5.1.2 Structural composite lumber flange materials complying with Specification [D5456](#).

5.1.3 Web materials complying with USDOC PS-1, USDOC PS-2, CSA O121, CSA O151, CSA O325, or CSA O437.0.

5.2 Flange Stock:

5.2.1 All flange material shall conform to the requirements of [6.4](#). In addition, when the flange material is structural composite lumber, the following properties shall be determined in accordance with Specification [D5456](#): modulus of elasticity (flat or edge, depending on flange orientation in the I-joint), compression (parallel and perpendicular to grain), and nail design values.

5.2.2 End joints in purchased flange stock are permitted provided such joints conform to the general intent and Section [10](#) of this specification.

5.3 *Web Material*—Panels shall conform to manufacturing or performance standards recognized by the applicable governing code. Examples are PS-1 (or CSA O151) and PS-2 (or CSA O325). In addition, all panels shall meet the equivalent of Exposure I requirements as specified in PS-1 or PS-2.

5.4 *Adhesives*—Adhesives used to bond together components of the finished product shall conform to the requirements in Specification [D2559](#) (or, in Canada, shall conform to an appropriate standard from the CSA Standards for Wood Adhesives, O112 Series, stipulated in CSA O86). In addition, adhesives used for web-to-web, web-to-flange, and flange-to-flange joints shall be qualified for heat durability performance in accordance with [5.4.3](#). [Appendix X4](#) gives additional information and standards that shall be considered when qualifying adhesives and adhesive-bonded materials.

NOTE 3—Heat durable performance implies that a bonded joint will exhibit similar material resistance to solid wood in an elevated temperature environment where the wood material surrounding the joint does not provide thermal protection.

5.4.1 Adhesives and binder systems used in the fabrication of Structural Composite Lumber products shall be evaluated in accordance with Specification [D5456](#).

5.4.2 Adhesives and binder systems used in the fabrication of panel products used as a web shall be evaluated in accordance with PS-2 (or, in Canada, CSA O325) with the Exposure 1 classification.

5.4.3 *Adhesives*—Heat durability:

5.4.3.1 Adhesives used for web-to-web, web-to-flange, and flange-to-flange joints shall be qualified for heat durability performance through testing in accordance with Test Method **D7247**. The test temperature and heat exposure duration for specimens tested at elevated temperature (7.2 of Test Method **D7247**) shall meet the requirements of Items 1, 2, 3, and 4 below.

(1) The solid wood control specimen and both pieces of the bonded specimen shall be prepared from the same commercial species group of Douglas Fir, Southern Pine, or the predominate commercial species group used in the flange. The adhesive formulation used in the test shall be the same as the adhesive formulation used in the production process.

(2) For the bonded specimens, the minimum target bondline temperature shall be 428°F (220°C). For the matched solid wood control specimens, the minimum target temperature at the shear plane shall be 428°F (220°C).

(3) The minimum target temperatures of Item 2 shall be maintained for a minimum of 10 min or until achieving a residual strength ratio for the solid wood control specimens of $30 \pm 10\%$, whichever is longer.

(4) Block shear testing shall be conducted immediately after removal from the oven such that the specimen bondline or shear plane temperature does not drop more than 9°F (5°C) after leaving the oven and prior to failure. This provision is satisfied when the time interval from the removal of the specimen from the oven to the failure of the block shear specimen does not exceed 60 s for each specimen tested and the room temperature of the test laboratory at the time of testing is not less than 60°F (15.5°C).

5.4.3.2 For adhesives tested in accordance with 5.4.3.1, the residual shear strength ratio for the bonded specimens, as calculated in accordance with Test Method **D7247**, shall be equal to or higher than the lower 95 % confidence interval on the mean residual shear strength ratio for the solid wood control specimens.

6. Qualification

6.1 *General*—This section describes procedures, both empirical and analytic, for initial qualification of the structural capacities of prefabricated wood I-joists. Qualification is required for certain common details of I-joist application since they often influence structural capacities. All capacities are to be reported with three significant digits. Any time significant changes in joist or application details, manufacturing processes or material specifications occur, qualification is required, as for a new manufacturer or product line.

6.1.1 *Testing*—Qualification tests shall be conducted or witnessed by a qualified agency as defined in 8.1. All test results are to be certified by the qualified agency.

6.1.1.1 *Sample Size*—The number of specimens specified in 6.2, 6.3, 6.4, 6.5, and 6.6 are minimums. The producer wishing to evaluate the validity of the sample size will find a procedure in 4.7 of Practice **D2915**.

6.1.1.2 *Test Specimens*—Materials and fabrication procedures of test specimens shall be as typical of intended production as can be obtained at the time of manufacturing qualification specimens. Minimum specimen temperature at the time of test shall be 40°F (4°C). Specimens shall be tested at the as-received moisture content.

NOTE 4—It is desirable to conduct preliminary tests to aid the selection of representative specimens.

6.1.1.3 *Test Accuracy*—Tests in accordance with this specification are to be conducted in a machine or apparatus calibrated in accordance with Practices **E4** except that the percentage error shall not exceed ± 2.0 .

6.1.1.4 *Test Methods*—Methods generally applicable to the full-section joist tests required herein are in Guide **E529**, with the following exceptions: (1) the methods are applicable to both qualification and quality control, (2) load rate shall be as specified in the following sections, and (3) delays between load increments are not required. Required tension and compression tests shall be substantially in accordance with Test Methods **D198** or Test Methods **D4761** with load rates as specified in the following sections. All test report formats and content shall be in keeping with the intended use of the results and be agreed upon by all involved parties prior to the test.

6.1.1.5 *Test Safety*—All full-scale structural tests are potentially hazardous and appropriate safety precautions must be observed at all times. One particular concern is the potential for lateral buckling during full-section I-joist tests and appropriate lateral restraint must be maintained at all times.

6.2 Shear Capacity Qualification:

6.2.1 Initial capacity shall be established from either test results or calculations. The equations used for the calculation method shall be confirmed by a test program; the details of which are beyond the scope of this specification. Explanations of the statistics used in the analysis of test results, with an example, are given in **Appendix X5**.

6.2.2 Factors which influence shear capacity include web type, thickness, and grade; web to flange joint; joint type in web (machined, butted, glued or not, reinforced, etc.). Each combination of these web factors must be tested separately in accordance with 6.2.3, unless the critical combination in a proposed grouping is first established by test. Flange stiffness influences shear strength: if a range of flange sizes is to be used with a given combination of web factors, all sizes must be tested unless all values are to be based on tests with the smallest flange. When a range of species or grades of either sawn or composite lumber is to be grouped, preliminary tests shall be conducted to determine which is critical. Joists with structural composite lumber flanges, such as laminated veneer lumber (LVL), must be tested separately from joists with sawn lumber flanges.

6.2.3 For each web factor combination, a minimum of ten specimens shall be tested for each critical joist depth. Critical joist depths are minimum and maximum product depths with approximate 4-in. (102-mm) depth increments between. If the installation of specific reinforcement as defined in the manufacturer's literature is required at a certain depth to maintain product performance in the progression of a series of depths

within a combination, the product must be tested at this depth plus the adjacent depth which does not require specific reinforcement.

6.2.4 Specimen length shall be that which usually produces failures in shear and shall not extend past each bearing support more than ¼ in. (6.4 mm). The bearing length shall be adequate to usually produce shear failure instead of a bearing failure but shall not exceed 4 in. (102 mm), unless justified. There shall be a minimum horizontal distance of 1½ times the joist depth between the face of the support and the edge of the load pad.

6.2.5 On one end of the specimen, a vertical web joint, if used, shall be located approximately 12 in. (305 mm) from the face of the support or ½ the distance between the support and the load pad.

6.2.6 The load shall be applied to the top flange either as a single point load at center span or as two point loads of equal distance from the center span. Load pads shall be of sufficient length to prevent local failure.

6.2.7 The load shall be applied at a uniform rate so that anticipated failure will occur in not less than 1 min.

6.2.8 Any required web reinforcements developed in 6.7.1 shall be installed at supports. When required to prevent failure at a load point, additional reinforcement shall be installed, provided such reinforcement is not wider than the load pad.

6.2.9 Ultimate load and mode of failure shall be recorded in addition to product and test setup descriptions. If any specimen fail in bending, the data shall be excluded. However, for purposes of evaluating shear capacity, bearing failure is considered a mode of shear failure. Appendix X6 discusses some of the modes of shear failure and offers a possible coding scheme.

6.2.10 The dead load of the specimen is to be included in the ultimate load calculation when specified by the producer.

6.2.11 The mean ultimate shear values shall show logical progression of strength as a function of depth. A linear regression analysis of the mean values shall have a coefficient of determination (r^2) of at least 0.9, or the specified tests of 6.2.3 must be repeated. If the second test set fails to meet the criteria, all depths which have been skipped must also be tested. (A check of the regression criteria is given in X5.4.5.)

6.2.11.1 Data from joist depths where failure is web buckling shall be excluded from the regression analysis, if: (1) including the results causes failure to meet the criteria of 6.2.11; or (2) the producer determines the reduction in regression line slope is unacceptable. In either case, all depths greater than the shallowest excluded, shall be tested.

NOTE 5—Depending on joist details and material, there will be some depth where web buckling appears as a mode of failure. Further increases in depth will result in consistent web buckling, and at some point ultimate strength will reduce compared to shallower joists.

6.2.11.2 When no more than three depths are to be qualified, the correlation is not necessary, but each depth must be tested.

6.2.12 The shear capacity of the product shall be limited to that calculated by taking into account sample size, test result variability, and reduction factors. Data from tests at different joist depths included in regression analysis are permitted to be combined to obtain a pooled estimate of variability.

6.2.12.1 *Combining Data*—The regression equation from 6.2.11 provides the expected mean shear strength (P_e) for depth (d_i):

$$P_e = A + Bd_i \quad (1)$$

where A and B are intercept and slope of the equation.

6.2.12.2 Where too few depths are involved for correlation in 6.2.11, when the tests fail the regression criteria, or where depths are excluded from the correlation, no combining is allowed and each such depth shall be evaluated separately.

6.2.12.3 The mean and standard deviation of the data from each depth tested are (\bar{P}_i) and (S_i). The coefficient of variation is:

$$v_i = S_i/\bar{P}_i \quad (2)$$

Let n_i be the number of tests for each depth (d_i) tested and included in the regression analysis. Then the coefficient of variation in the combined data sets is:

$$v = \sqrt{\frac{\sum[(n_i - 1) v_i^2]}{\sum n_i - J}} \quad (3)$$

Where J is the number of depths included in the regression analysis and the summation is from $i = 1$ to J .

6.2.12.4 *Shear Capacity*—The shear capacity is calculated as follows:

$$P_s = C(P_e - KvP_e)/2.37 \quad (4)$$

where:

K = factor for one-sided 95 % tolerance limit with 75 % confidence for a normal distribution. Values for this factor are given in Appendix X5, Eq X5.20, and Table X5.3;

P_e = ultimate mean shear strength from Eq 1 or the mean of any depth in accordance with 6.2.12.2;

v = coefficient of variation of combined data from Eq 3 or, in accordance with 6.2.12.2, from Eq 2 when any depth is evaluated alone;

C = product of any appropriate special use reduction factors from Appendix X7; and

P_s = shear capacity.

6.2.12.5 When data are combined, the factor K is based on a sample size $N = \sum n_i - J$. When the criteria of 6.2.11 are not met and for depths excluded from the regression analysis, then the allowable shear capacity is computed separately for each such depth and is:

$$P_s = C(\bar{P}_i - Kv_i\bar{P}_i)/2.37 \quad (5)$$

and the factor K is for a sample size of n_i . A discussion of the reduction factor (2.37) is given in Appendix X7.

6.3 *Reaction Capacity Qualification*—Reaction capacity shall be determined in accordance with Annex A1.

6.4 *Moment Capacity Qualification*—Moment capacity shall be determined either analytically from the characteristics of flange material (6.4.1) or empirically from the results of I-joist bending tests (6.4.3).

6.4.1 *Analytical Method*:

6.4.1.1 In this method, the I-joist moment capacity is determined as follows:

$$M_a = K_L F_a A_{net} y \quad (6)$$

where:

- K_L = length adjustment factor, computed in accordance with 6.4.1.5. The factor adjusts flange material F_a as a function of joist span and stress. Joist depth, tension test gage length, finger joint spacing, and material or joint variability are utilized in determining K_L ;
- A_{net} = net area of one flange (excluding areas of all web material and rout);
- y = distance between flange centroids (with the rout removed); and
- F_a = design flange axial stress, taken as the lower of flange tensile stress adjusted to the reference gage length or end joint tensile stress computed in accordance with 6.4.1.4, or flange compressive stress computed in accordance with 6.4.1.6.

NOTE 6—The assessment of axial stress on the basis of average stress at a given cross section matches committee judgment and experimental evidence based on joists in which the thickness of an individual flange is less than approximately one sixth of the overall joist depth. For joists not meeting this criterion, additional consideration of extreme fiber stresses may be needed.

NOTE 7—The information in this specification is not intended to be limited to the allowable stress design (ASD) format. Provided that appropriate scaling of design values is completed (from ASD to the limit states design (LSD) or load and resistance factor design (LRFD) format) in accordance with applicable standards.

6.4.1.2 *Flange Material Types*—Flange materials fall into one of the following three categories:

(1) *Standard Lumber Grades; Standard Lengths*—Flanges utilizing nominal 8-ft (2.44-m) and longer sawn lumber of a standard grade permitted by the governing code and graded under standards recognized by American Lumber Standards Committee (ALSC) or Canadian Lumber Standards Accreditation Board (CLSAB). The tabulated allowable tension value, F_p , is assumed to be based on a 12-ft (3.66-m) gage length. End joints, when used, shall be qualified in accordance with 6.5.

(2) *Nonstandard Grades; Standard Lengths*—Flanges utilizing nominal 8-ft (2.44-m) and longer structural composite or sawn lumber, but not meeting the standard grade criteria of 6.4.1.2 (1). Qualification testing and analysis shall be in accordance with 6.4.1.3 and 6.4.1.4. End joints, when used, shall be qualified in accordance with 6.5. Alternatively, a single end joint, when used, shall be permitted to be included within the gauge length of each flange specimen when tested in accordance with 6.4.1.3. To use this alternative method, the minimum end-joint spacing permitted in application and used to determine L_1 in 6.4.1.5 shall be the tested gage length.

(3) *Any Grades; Short Lengths*—Flanges utilizing structural composite lumber or sawn lumber in lengths shorter than 8 ft (2.44 m) before end jointing. Qualification testing and analysis shall be in accordance with 6.4.1.3 and 6.4.1.4. Qualification specimens shall be used to establish a characteristic (that is, average) joint spacing as noted in Eq 7. Average joint spacing in individual flanges in the qualification sample

shall not be less than 75 % of the established characteristic joint spacing. The characteristic joint spacing established during qualification shall be maintained in subsequent production.

$$L_j = L/N \quad (7)$$

where:

- L_j = characteristic joint spacing,
- L = total length of flange in the gage length for the qualification sample, and
- N = total number of joints in the gage length for the qualification sample.

6.4.1.3 *Tension Tests*—For flange material conforming to 6.4.1.2 (2) or (3), tension tests parallel to grain shall be conducted on a gage length (distance between grips) of not less than 8 ft (2.44 m) for sawn lumber and 3 ft (0.91 m) for structural composite lumber. When flanges utilize sawn lumber or structural composite lumber less than 8 ft long, the characteristic end joint spacing for the qualification sample shall comply with the provisions of 6.4.1.2 (3). Testing speed shall be in accordance with 28.3 of Test Methods D4761. The minimum sample size shall be 53. The flange material variability (coefficient of variation) and tension gage length shall be reported.

NOTE 8—SPS-4 provides alternative methods which comply with the intent of characteristic joint spacing and minimum gage length provisions of 6.4.

6.4.1.4 *Capacity*—The tensile capacity shall be the lower 5 % tolerance limit with 75 % confidence, divided by 2.1. The lower 5 % tolerance limit shall be established with 75 % confidence using either parametric or nonparametric procedures; however, if parametric procedures are adopted, an appropriate analysis used to confirm the type of distribution must be presented. Minimal evidence that a distribution fits the data shall consist of a cumulative plot of the data with the chosen distribution superimposed on the data. The latter shall be either a curve as shown in Fig. X5.1 or a linearized plot as shown in Fig. X5.5.

6.4.1.5 The length adjustment factor K_L is the lesser of 1.0 or the value computed as follows:

$$K_L = K_S (L_1/L)^z \leq 1.0 \quad (8)$$

where:

- K_L = length adjustment factor;
- K_S = stress distribution adjustment factor (adjusts design flange axial stress (F_a) from full-length constant stress (such as a tension test) to the reference stress condition = 1.15;
- L_1 = gage length, (in.). For 6.4.1.2 (1) utilizing flange stress, $L_1 = 144$ in. (3658 mm). For 6.4.1.2 (2) utilizing flange stress, $L_1 =$ distance between tension tester grips. For 6.4.1.2 (3) utilizing flange stress, $L_1 =$ distance between tension tester grips. For 6.4.1.2 (1) and (2) utilizing end joint stress, $L_1 =$ minimum end joint spacing allowed in the I-joist;
- L = joist span = 18 times the joist depth (in.); and
- Z = exponent for Eq 8 in accordance with Table 1.

TABLE 1 Exponent (Z) for Eq 8^A

COV ^{B,C} , %	Z
≤10	0.06
15	0.09
20	0.12
25	0.15
≥30	0.19

^A Interpolation between tabular values is permitted.

^B Coefficient of variation of the full data set based on a normal distribution, taken as not less than the higher COV attained from the tensile strength of flange material or end joints.

^C Coefficient of variation for 6.4.1.2 (1) material shall be 20 % for machine-graded lumber (including SPS-4 material) and 25 % for visually graded lumber.

NOTE 9— K_L is not intended for use as an adjustment factor for specific application lengths. It is a modifier for assigning design I-Joist moment capacity by depth. (See Eq 6.)

6.4.1.6 Values for compression shall be established by testing the material in tension and assigning a value in compression such that:

$$F_{ci} = F_{ti}(F_c/F_t) \quad (9)$$

where:

F_t = closest assigned code value in tension for same species and size as tested pieces;

F_c = code assigned value in compression for same grade, species, and size as F_t visual grades;

F_{ti} = tensile value as determined in 6.4.1.3; and

F_{ci} = allowable stress in compression.

If F_{ti} is larger than the highest value given in tables of visual grade lumber for the species, then the ratio of tension to compression shall be from tables for the nearest machine stress rated (MSR) lumber grade.

6.4.2 Analytical Method Confirming Tests:

6.4.2.1 It is required that a minimum of ten I-joist specimens be tested at each of the extremes of flange size, allowable stress, and joist depth. This testing is not intended to substantiate the moment capacity determined in 6.4.1, but is considered necessary for any new product to generally confirm the overall performance of the assembled components. This testing is also necessary to satisfy the requirements of 6.6.

6.4.2.2 Test setup and procedures shall conform to the requirements of 6.4.3, except that loading may simulate uniform load with load points spaced no greater than 24 in. (610 mm) on center. In addition, the maximum permitted web hole specified in 6.4.3.2 is optional.

6.4.2.3 Any specimen failing at a calculated maximum moment of less than 2.1 times the calculated capacity indicates the possibility of errors in manufacturing, material selection, or calculation. The reason for such failures shall be carefully evaluated and probable cause determined. Further testing shall be conducted as indicated in 6.4.2.4 and 6.4.2.5.

6.4.2.4 If the determined probable cause identified in 6.4.2.3 results in manufacturing or design changes of the product, retesting shall be conducted in accordance with 6.4.2.1.

6.4.2.5 If a probable cause is not found and the low result cannot be attributed to errors that can be corrected, further testing shall be conducted. A minimum of 10 additional samples for parametric analysis or 43 additional samples for nonparametric statistics shall be tested. The tested moment capacity shall be the lower 5 % tolerance limit with 75 % confidence divided by 2.1. To confirm the analytical method,

the tested moment capacity shall be greater than or equal to the calculated moment capacity determined in 6.4.1.1.

NOTE 10—Although it is unlikely that in a ten-specimen confirming test of a controlled manufacturing process, a result below 2.1 times the calculated capacity will be encountered, it is statistically possible that such a specimen could appear. Increasing the sample size and applying parametric or nonparametric procedures to analyze the data will determine if changes to the analytical moment capacity are needed. (See commentary in X2.5.3.)

6.4.3 Empirical Method:

6.4.3.1 *Test Procedure*—Bending tests are to be conducted on a span of 17 to 21 times the joist depth. Two point loads are to be placed symmetrically about the center and the spacing between such load points shall be a minimum of one third of the span. Joists shall be reinforced under the load points when necessary to prevent local failure. Load rate shall be adjusted to produce failure in not less than 1 min. Maximum moment in the specimen and the location of failure shall be recorded.

NOTE 11—A span to depth ratio of 18 is a frequent international practice.

6.4.3.2 *Specimens Tested*—Specimens shall be typical of intended production. Each flange material, grade, dimension, species and supplier, combined with each web type, thickness and grade, shall be tested. Procedures for evaluating materials from each supplier shall be addressed in the manufacturing standard. One method of evaluation is shown in X2.1.1.8. When flanges contain end joints, such joints shall have been qualified in accordance with 6.5.1, and all bending test specimens shall include at least one joint in the tension flange located between the load points. When holes are allowed in the web in accordance with 6.7, the maximum permitted hole shall be located approximately at the center of the span. Sufficient bearing length or reinforcement, or both, shall be provided at supports to prevent bearing failures.

6.4.3.3 *Remanufactured Solid Sawn Flanges*—When flanges utilize remanufactured lumber, the specimens tested shall be typical of the specifications in the manufacturing standard in accordance with 9.1.1.1.

NOTE 12—It is strongly recommended that plant personnel performing regrading activities be trained by an agency under an accreditation program such as the ALSC.

6.4.3.4 *Sample Size and Analysis*—For qualification, a minimum of 28 specimens are required in each tested depth. Testing shall be at joist depth intervals no greater than 3 in. (76 mm), with a minimum of four depths tested, including the minimum and maximum joist depths. The mean ultimate moment capacities shall show logical progression as a function of the depth squared. A linear regression analysis of the mean values shall have a coefficient of determination (r^2) of at least 0.9. If the manufacturer produces less than 4 depths, 53 specimens of each depth shall be tested, but the requirement for a coefficient of determination shall not apply. Moment capacity shall be based on the lower 5 % tolerance limit with 75 % confidence, divided by 2.1. Nonparametric statistics shall be used to determine the tolerance limit and confidence unless justification is presented for using parametric procedures. Joist depths not tested shall be assigned capacities based on a logical

progression of the depth squared between values assigned at the nearest depths tested to either side.

6.5 End Joint Qualification:

6.5.1 *Standards*—Adhesives used in joints shall conform to the requirements of 5.4.

6.5.2 *Testing*—Tension tests parallel to grain, on full-section joints, shall be conducted on a gage length (distance between grips) of not less than 2 ft (0.61 m). Testing speed shall be in accordance with 28.3 of Test Methods D4761. The minimum sample size shall be 53. The design stress shall be determined from 6.4.1.4. End joint variability (coefficient of variation) shall be reported.

6.5.3 *Requirements*—Joints in any flange material shall conform to this specification, with particular reference to Section 10 when applicable.

6.6 Stiffness Capacity and Creep:

6.6.1 *Tests*—The tests of 6.4.2 or the first ten tests at the extremes of depth in accordance with 6.4.3 shall be used to confirm stiffness capacity and evaluate creep characteristics. Center span deflection measurements shall be recorded at a minimum of four increments to 1½ times expected moment capacity at time of qualification.

6.6.2 *Stiffness Capacity*—Any formula which accurately predicts the effects of both bending and shear deformation is permitted to be used. The equation must be adjusted when the mean of the ratios of test deflections at moment capacity load (determined from a least square line fitted through the data points), to predicted deflection is more than $1.0 + S/\sqrt{N}$, where S is the standard deviation of the ratios of test to predicted deflections and N is the total number of deflection tests conducted.

NOTE 13—Usually, a required adjustment will be applied only to the flange modulus of elasticity (MOE) used in the equation. For stiffness-limited applications of I-joists, the largest percentage of deflection is typically attributed to bending, and because of the section geometry, the principle elastic modulus is that of the flange material. Therefore, here and in Sections 9 and 11, emphasis is placed on the flange MOE.

6.6.2.1 *Elastic Properties*—Mean values are to be used in the deflection equation (1) when flange modulus of elasticity cannot be obtained from tables of recognized values, it shall be obtained from tests of the flange material used to establish moment capacity in accordance with 6.4.1; or (2) when moment capacity is determined in accordance with 6.4.3, the flange MOE shall be obtained from tables of recognized values or tests of the flange material. (3) Elastic properties of the web material shall be obtained from the appropriate standard.

6.6.3 *Creep*—Two of the I-joist specimens shall be loaded to 20 % of their moment capacity and center-span deflection readings taken. For purposes of this test, 20 % is assumed to be typical basic dead load (BDL). The specimen shall then be loaded to 1½ times the moment capacity for 1 h and deflection readings taken. The specimen shall be unloaded to BDL and deflection readings shall be taken after 15 min. The specimens must recover an average of 90 % of the total deflection from BDL to the end of the 1-h load period.

6.7 Details of End Use:

6.7.1 The intent of this section is to define common application details. In addition to the following minimum

considerations, other details which affect application performance shall be investigated (for example, minimum nail spacing to avoid splitting).

6.7.2 Web Openings:

6.7.2.1 Holes which remove a significant portion of the web will reduce shear strength at that section of the I-joist. Tests are to define such reductions for varying size and shape openings so that in application, openings can be located at sections subjected to appropriate shear levels. A minimum of five specimens of at least three depths encompassing the product range shall be tested for each depth/opening combination. Test specimens and setup are permitted to be the same as specified in 6.2 with an opening located between support and load points and centered on a web joint, when web joints exist in the product.

6.7.2.2 Maximum size hole which can be located anywhere in the web, shall be specified by the manufacturer and supported by data.

6.7.2.3 Spacing of allowed multiple holes must be verified by test.

6.7.3 *Special Details*—Depending on joist configuration, concentrated loads require local reinforcement. Loads supported by connection to the web or applied to the bottom flange require special consideration and appropriate details. These and other special conditions of application require appropriate evaluation and testing to ensure the safety provisions of this specification are maintained.

7. Design Values

7.1 *Design Value Limited*—Design values are determined from the analysis and capacities as specified in this specification. In no case shall a design value exceed the capacity determined in Sections 6 or 11. (See definitions of capacity and design value in 3.1.1.)

7.2 *Design Value*—It is the responsibility of the I-joist producer to determine design values. Judgment is required particularly when assessing design values from qualification tests. Design values shall consider potential low-line lot capacities to avoid marginal application performance or un economical reject rates in the quality assurance program.

8. Independent Inspection

8.1 A qualified agency shall be employed by the manufacturer to audit the quality assurance program and inspect the production process of the plant without prior notification or with minimal prior notification. The audit and inspection shall include review and approval of the plant's quality assurance program and inspection of randomly selected products and QC data. When production is sporadic, the qualified agency shall communicate with the manufacturer to schedule inspections to coincide with production.

8.2 A qualified agency is defined as one that:

8.2.1 Has been accredited by an International Accreditation Forum (IAF) accreditor as meeting ISO/IEC 17020 requirements;

8.2.2 Has trained technical personnel to verify that the grading, measurement, species, construction, shaping,

bonding, workmanship, and other characteristics of the products as determined by inspection, sampling, and testing comply with all applicable requirements specified herein;

8.2.3 Has procedures to be followed by its personnel in performance of the inspection and testing; and

8.2.4 Has no financial interest in, or is not financially dependent upon, any single company manufacturing the product being inspected or tested;

8.2.5 Is not owned, operated, or controlled by any such company.

9. In-House Quality Assurance

9.1 *Manufacturing Standard:*

9.1.1 A manufacturing standard shall be written and maintained for each product and each production facility and shall be the basis for the qualified agency's specific inspection at that location. As a minimum, it shall include the following:

9.1.1.1 Material specifications, including incoming inspection and acceptance requirements, and specifications for re-grading flange stock when applicable,

9.1.1.2 Process controls for each operation in production of the product,

9.1.1.3 Quality control, inspection and testing procedures, and frequencies, and

9.1.1.4 Finished product identification, handling, protection, and shipping requirements.

9.1.1.5 When applicable, the minimum permitted flange joint spacing shall be specified.

9.2 *Inspection Personnel*—All in-house persons responsible for quality control shall demonstrate to the satisfaction of the qualified agency that they have adequate knowledge of the manufacturing process, of the inspection and test procedures used to control the process, of the operation and calibration of the recording and test equipment used, and of the maintenance and interpretation of quality control records.

9.3 *Record Keeping*—All pertinent records shall be maintained on a current basis and be available for review by both in-house and qualified agency inspection personnel. As a minimum, such records shall include:

9.3.1 All inspection reports and records of test equipment calibration whether accomplished by in-house or qualified agency personnel,

9.3.2 All test data, including retests and data associated with rejected production, and

9.3.3 Details of any corrective actions taken and the disposition of any rejected production, resulting from tests or inspections.

9.4 *Testing Equipment*—Testing equipment is to be properly maintained, calibrated, and evaluated for accuracy and adequacy in accordance with 6.1.1.3, at a frequency satisfactory to the qualified agency.

9.5 *I-Joist Quality Control Testing:*

9.5.1 *Objectives*—The following objectives are to be met simultaneously with the quality-control testing program:

9.5.1.1 Provide test data for use in maintaining and updating design values, and

9.5.1.2 Verify production process and material quality on a daily basis.

9.5.2 *Initial Quality Control*—When qualification is based on no more than the minimum testing required in this specification, the producer shall initiate higher test frequencies and retest levels. All new producers are advised to intensify quality control in early production.

9.5.3 *Required Tests*—The following shall be the scope of a minimum testing program:

9.5.3.1 Test methods shall be identical to those of Section 6.

9.5.3.2 The shear strength test described in 6.2 shall be used for quality control of shear strength. This test is required even if qualification is by calculation.

9.5.3.3 If flanges contain end joints qualified in accordance with 6.5, daily tension tests of full-section joints shall be conducted and failure loads recorded. The manufacturing standard must include the characteristic joint spacing that will be maintained in production. Durability tests of such joints are required only at such frequency as required to verify adhesive performance in accordance with 5.4.

9.5.3.4 When flange material is qualified by test in accordance with 6.4.1.2 (2) or 6.4.1.2 (3), the testing of that section shall be included in daily quality control tests. In all cases, QA provisions shall be established to maintain qualification strength.

9.5.3.5 When moment capacity is determined empirically, the test detailed in 6.4.3 shall be conducted as part of the daily quality-control program. All depths produced shall be tested in this program, and the tests shall include deflection measurement.

9.5.3.6 When the flange material does not have a modulus of elasticity assigned by the code, stiffness measurement of the material shall be part of the quality-control program.

9.5.4 *Data Collection and Analysis*—Test frequency, minimum test values, and rejection criteria for all tests of 9.5.3 shall be chosen to yield quality-control performance which is consistent with design values assigned to the product and its intended use.

10. Qualification and Quality Assurance of I-Joist Components Manufactured by Others

10.1 *Producer's Responsibility*—When the I-joist producer purchases material which would require qualification and quality control under the provision of this specification, the I-joist producer shall be responsible for assuring that, as a minimum, such material conforms to the requirements of Sections 6, 8, 9, and 11 of this specification.

10.2 *Record Keeping*—The I-joist producer shall obtain and maintain records of certification from the outside producer's qualified agency that the components supplied conform to the requirements of this specification.

10.3 *Identification*—All such components shall be appropriately marked as agreed upon between the component and I-joist producers.

11. Periodic Reevaluation of Structural Capacities

11.1 *Reevaluation Required*—Each capacity monitored by the required tests of 9.5.3 shall be reevaluated on a periodic

basis. As a minimum, reevaluation shall be accomplished at the end of the first six months of production by any new manufacturer and for any new product line, and thereafter each such capacity shall be reevaluated and audited by the qualified agency at the end of each successive year of production.

11.1.1 *Reaction Capacity Reevaluation*—A one-time reevaluation of reaction capacity shall be accomplished at the end of the first six months of production by any new manufacturer and for any new product line. The reevaluation is to be based on data from specimens selected randomly throughout the six-month period and tested when convenient. Tests are to be conducted in accordance with 6.3.

11.1.2 *Regraded Solid Sawn Lumber Flanges*—As a minimum, reevaluation shall be conducted every six months for regraded solid sawn lumber flanges as described in 6.4.1.2. The testing shall be that specified in 9.5.3.4 and the test data shall be evaluated in accordance with 6.4.1.4.

11.2 *Minimum Data Base in Periodic Evaluation:*

11.2.1 *Shear and Flange Material Tests*—The minimum number of tests to be included in the analysis is that required for qualification in accordance with Section 6. When it becomes apparent that this requirement will not be met by the initial test frequency established, the frequency of testing shall be increased. Evaluation of test frequency shall be accomplished early in the evaluation period to ensure that test data is representative of production in the period and will be randomly accumulated at time intervals spaced throughout the period.

11.2.2 *Empirical Moment Capacity Tests*—Reevaluation shall be conducted every three months and the minimum number of tests required is that used for qualifying in 6.4.3. Test frequency in the period must be adjusted as necessary to ensure the minimum number of tests are met. If data on the full range of depths is not available, additional depths shall be selected and tested so that the data available is at least equal to that required in 6.4.3, except that if the coefficient of determination (r^2) is at least 0.9 as described in 6.4.3.4, the data for joists where the only change is depth may be combined provided a minimum of 112 tests are conducted every 60 production days, but in a period not to exceed 6 calendar months. Details of how suppliers are reevaluated shall be a part of the manufacturing standard.

11.3 *Data Analysis*—Data to be included in the analysis is that developed in the latest evaluation period from the testing

specified in 9.5.3. Test data which was cause for rejection of a production lot shall be excluded, unless a reduced design value and associated reject level is to be established by the reevaluation. Also, with the agreement of the qualified agency, low test values related to any assignable and correctable cause which has been corrected, shall be excluded from consideration. Analysis of the data shall be identical to that of the applicable qualification section of this specification.

11.3.1 *Flange Strength Distributions*—Flange strength data from the period, including joint strength when applicable, shall be evaluated. If the coefficient of variation of production has increased by more than 1½ % since the last evaluation, the evaluation of 6.4.1.5 shall be repeated and design moment shall be adjusted or corrective action taken that is acceptable to the qualified agency.

11.4 *Adjustment of Design Value*—If the capacity determined in the analysis of 11.3 is less than the current design value, the design values must be reduced or corrective action taken that is acceptable to the qualified agency. When stiffness capacity is determined from flange material stiffness tests or joist bending tests, the comparison shall be between the mean of the tests in the period and the design value; the flange modulus of elasticity in the design equation shall be reduced proportionately when the current test mean is less than the design value.

12. Installation Instructions

12.1 Proper installation instructions or drawings shall accompany the product to the final job site. They shall include any special instructions required for the product, and weather protection and handling requirements. In cases where web reinforcement and attachment requirements, lateral support details, bearing or connection requirements, and web hole cutting limits are not covered by adequate general notes, standard sketches and charts shall be included with the installation instructions, or specific job drawings shall properly cover these requirements.

13. Identification

13.1 The product shall be clearly and properly identified by product name, company name or logo, plant location or number, qualified agency name or logo, and a means for establishing the date of manufacture.

FIG. A1.1 End Reaction Test Set-up (non-symmetric set-up allows for two end-bearing tests per specimen)

ANNEX

(Mandatory Information)

A1. ESTABLISHING REACTION CAPACITIES FOR PREFABRICATED WOOD I-JOISTS

A1.1 Scope

A1.1.1 **Annex A1** provides empirical procedures for establishing the reaction capacity of prefabricated wood I-joists. Derivation by an analytical model is beyond the scope of **Annex A1**.

A1.1.2 Explanations of the statistics used in the empirical analysis of test results, with examples, are given in **Appendix X8** and **Appendix X9**.

A1.1.3 **Annex A1** does not preclude the development of alternative reaction qualification procedures meeting the intent of **Annex A1**. Documentation showing equivalency to each of the qualification requirements in **Annex A1** shall be provided and agreed upon with the manufacturer’s qualified agency.

A1.1.4 **Annex A1** was developed in light of currently manufactured products, produced from materials defined in Section 5. New materials may require new or revised procedures to provide comparable levels of safety and performance.

A1.2 Wood I-Joist Reaction Capacity Qualification

A1.2.1 Factors that influence reaction capacity include bearing length, web (type, orientation, thickness, and grade), rout geometry, adhesive type, joist depth, and flange (type, size, species, and grade). Each combination of these factors should be tested separately according to A1.2.4, unless the critical combination is first established by test. Joists with structural composite lumber flanges must be tested and analyzed separately from joists with sawn lumber flanges.

A1.2.2 Qualification testing for both end and intermediate reaction capacity shall be undertaken and analyzed as independent test programs.

A1.2.3 The minimum sample size for either an end or intermediate reaction capacity qualification program shall be 40 for a series of I-joists with the same materials except for the joist depth. The test specimens shall be evenly divided into groups that represent the extremes of bearing length and joist depth to be qualified. Extrapolation beyond the tested extremes of bearing length and joist depth shall not be permitted.

NOTE A1.1—Bearing lengths less than 1.5 in. are not recommended due to concerns regarding construction tolerances and building code requirements.

A1.2.4 End and intermediate reaction capacity qualifications shall follow either the “Default” or “Regression-Based” procedures. Any data set that does not support the minimum coefficient of determination (r^2) requirement for a Regression-Based qualification shall be re-analyzed as a Default qualification.

A1.2.4.1 *Default Qualification*—A Default qualification shall be conducted by testing independent groups at the extremes of bearing length and joist depth to be qualified. Additional test groups are permitted to be added to the program provided that the minimum sample size in each additional group is 10 and the minimum sample size for the entire I-joist series is 40. Each group shall be analyzed independently to determine a design value using the procedures of A1.4.5.

NOTE A1.2—The following represent typical Default test programs that would meet the minimum sampling criteria to qualify a joist series for end or intermediate reaction capacity: four test groups with $n = 10$ at the extremes of bearing length and depth to qualify a range for both variables, two test groups with $n = 20$ when one bearing length will be qualified for a range of depths, and one test group with $n = 40$ when only a single bearing length and depth are qualified.

A1.2.4.2 *Regression-Based Qualification*—In a Regression-Based qualification, a manufacturer shall establish that reaction capacity is a linear function of bearing length. At a minimum, the test program shall include the shallowest and deepest joist depths to be qualified. At least three evenly spaced increments of bearing length ($\pm 10\%$) shall be evaluated for each joist depth tested. Provided that the resulting regressions maintain a minimum r^2 of 0.9 for each joist depth, they may be reduced to a design equation using the procedures of A1.4.6.

NOTE A1.3—A typical Regression-Based test program to establish end or intermediate reaction capacity shall consist of six groups with $n = 7$ for each group. A minimum of three bearing lengths shall be tested at the maximum and minimum joist depths to be qualified. The data for each depth shall be combined using a linear regression to define reaction capacity as a function of bearing length at the extreme depths.

A1.3 Test Methods

A1.3.1 *End Reaction*—Specimens shall be tested according to either Fig. A1.1 or Fig. A1.2. The test span shall be that which usually produces end reaction failures. Fig. A1.1 allows for one overhang no longer than $\frac{1}{2}$ the test span. A single concentrated load shall be placed off-center toward the test

FIG. A1.2 End Reaction Test Set-up (symmetric set-up allows for one end-bearing test per specimen)

FIG. A1.3 Three-Point Intermediate Reaction Test Set-up

reaction. This set up allows the joist to be turned end-for-end to perform a second test, with the failed end as the overhang for the second test. In Fig. A1.2, the load shall be applied at the center of the test span as either a single concentrated load as shown, or as two concentrated loads placed symmetrically about the center of the test span. Fig. A1.2 allows for only one test per specimen. For both Figs. A1.1 and A1.2, the applied load shall have a clear distance of at least 1.5 times the joist depth, d , between the inside face of the test reaction and the edge of the load pad. The load shall be applied at a uniform rate so that anticipated failure will not occur in less than 1 min. The I-joist specimens shall have bearing lengths and web stiffeners installed at the test reactions that are consistent with the end reaction condition to be evaluated. The reaction fixtures of the test frame shall be smooth, hard, and flat surfaces that are wide enough to provide full vertical support for the flange as it fractures without creating out-of-plane lateral interference that impacts the failure. The load pad shall be of sufficient length to prevent local failure under the load point. Additional web reinforcement is permitted at the load point and non-test reaction to prevent local failure provided the reinforcement is not wider than the length of the load pad or reaction surface. Out-of-plane lateral restraints may be provided for the flanges at the reactions and as necessary within the span to prevent a flange buckling failure. Lateral restraints shall not restrict the in-plane movement of the joist. Load cells shall record the test reaction (half the total applied load is appropriate for setup shown in Fig. A1.2). Perforated knockouts (1½ in. maximum

diameter) shall be randomly located within the joist specimen, as they would occur in application. Web-to-web joints are permitted to be randomly located when shear capacity is qualified using an independent test program. Otherwise, a web joint shall be positioned at the mid-point between the edge of the load and reaction plates.

A1.3.2 *Intermediate Reaction*—Specimens shall be tested according to either Fig. A1.3 or Fig. A1.4. The test span(s) shall be that which usually produces intermediate reaction failures. In Fig. A1.3, the load shall be applied at the center of the test span through a surface that represents the intermediate reaction condition to be evaluated. In Fig. A1.4, the loads shall be applied symmetrically about the test reaction through load pads of sufficient length to prevent local failure under load points. With both test setups, the I-joist specimens shall have bearing lengths and web stiffeners installed at the test reactions that are consistent with the intermediate reaction condition to be evaluated. The fixtures of the test frame at the test reactions shall be smooth, hard, and flat surfaces that are wide enough to provide full vertical support for the flange as it fractures without creating out-of-plane lateral interference that impacts the failure. For both Figs. A1.3 and A1.4, the applied load(s) shall have a clear distance of at least 1.5 times the joist depth, d , between the inside face of the reaction and the edge of the load surface. The load shall be applied at a uniform rate so that anticipated failure will not occur in less than 1 min. Additional web reinforcement is permitted at the non-test reactions and load points to prevent local failure provided the reinforcement is not wider than the length of the load or reaction surfaces. Out-of-plane lateral restraints may be provided for the flanges at the reactions and as necessary within the span to prevent a flange buckling failure. Lateral restraints shall not restrict the in-plane movement of the joist. Load cells shall record the test reaction (the sum of both reactions is appropriate for setup shown in Fig. A1.3). Perforated knockouts (1½ in. maximum diameter) shall be randomly located within the joist specimen, as they would occur in application. Web-to-web joints are permitted to be randomly located when shear capacity is qualified using an independent test program. Otherwise, a web joint shall be positioned at the mid-point between the edge of the load and reaction plates.

A1.3.3 Ultimate loads and modes of failure shall be recorded.

A1.4 Data Analysis

A1.4.1 Each end and intermediate reaction qualification data set shall be independently analyzed.

A1.4.2 Bending failures are permitted to be excluded from the data set. However, the minimum sample size provisions of A1.2.3 shall be maintained after any exclusion.

A1.4.3 The mean (P_i) and standard deviation (S_i) shall be calculated for each individual test group. The coefficient of variation (COV) for each group is defined as:

$$v_i = \frac{S_i}{P_i} \quad (A1.1)$$

FIG. A1.4 Five-Point Intermediate Reaction Test Set-up

A1.4.4 The analysis of data from either a Default or Regression-Based qualification require the COV from individual test groups be combined into a single COV as part of the design value derivation process as outlined in A1.4.5 and A1.4.6, respectively. No combined COV shall be less than the minimum permitted COV, v_{min} . v_{min} shall be equal to 0.10 for an end bearing qualification and 0.08 for an intermediate bearing qualification.

NOTE A1.4—Due to the limited qualification samples and lack of ongoing quality assurance requirements, the specified minimum coefficients of variation (v_{min}) are intended to provide a rational coefficient of variation for I-joist reaction capacities and were established based on committee judgments.

A1.4.5 *Specific Analysis Provisions For a Default Qualification:*

A1.4.5.1 The combined COV for an end or intermediate reaction qualification data set shall be computed as:

$$v_d = \sqrt{\frac{\sum [(n_i - 1)v_i^2]}{\sum n_i - J_d}} \geq v_{min} \quad (A1.2)$$

where:

- v_d = combined COV for the end or intermediate reaction data set in a Default qualification,
- n_i = sample size within an individual test group,
- v_i = COV for an individual test group,
- v_{min} = minimum combined COV permitted ($v_{min} = 0.10$ for end reaction, $v_{min} = 0.08$ for intermediate reaction), and
- J_d = total number of groups tested in a Default qualification.

A1.4.5.2 The design reaction capacity for each tested group shall be individually computed as:

$$P_B = \frac{C \cdot P_i (1 - K v_d)}{2.37} \quad (A1.3)$$

where:

- P_B = design reaction capacity within a tested group, lb;
- P_i = mean reaction capacity within a tested group, lb;
- v_d = combined COV for the Default test program from A1.4.5.1;
- K = factor for one-sided 95 % tolerance limit with 75 % confidence for a normal distribution based on the sample size for the individual test group being analyzed (n_i). Values for this factor are given in Appendix X5, Eq X5.20, and Table X5.3. ($K = 2.104$ for $n_i = 10$); and

C = product of appropriate special use reduction factors from Appendix X7.

A1.4.5.3 Design reaction capacities for bearing lengths and joist depths between the tested groups are permitted to be linearly interpolated. Extrapolation beyond the tested extremes of bearing length and joist depth is not permitted.

A1.4.6 *Specific Analysis Provisions For a Regression-Based Qualification:*

A1.4.6.1 Shear failures are permitted to be excluded from the data set provided that shear capacity is qualified using an independent test program and the sample size provisions of A1.2.3 are maintained.

A1.4.6.2 Data sets that show different reaction capacities for different joist depths shall have independent linear regressions developed for each of the tested depths. Data sets that do not show different reaction capacities for different joist depths shall have the data from all of the tested depths combined into a single regression that covers the full range of depths included in the qualification.

A1.4.6.3 Linear regressions shall be developed to define the relationship between bearing length and reaction capacity that take the following form:

$$P_e = A + B b_i \quad (A1.4)$$

where:

- P_e = predicted ultimate mean reaction capacity, lb;
- b_i = bearing length, in.;
- A = equation intercept, lb; and
- B = equation slope, lb/in.

A1.4.6.4 A combined COV shall be computed for each regression equation developed using the following:

$$v_r = \sqrt{\frac{\sum [(n_i - 1)v_i^2]}{\sum n_i - J_r}} \geq v_{min} \quad (A1.5)$$

where:

- v_r = combined COV for a linear regression,
- n_i = sample size within an individual test group,
- v_i = COV for an individual test group,
- v_{min} = minimum combined COV permitted ($v_{min} = 0.10$ for end reaction, $v_{min} = 0.08$ for intermediate reaction), and
- J_r = number of tested bearing lengths combined into a single regression.

A1.4.6.5 Each regression from A1.4.6.3 shall be reduced to a design regression using the following:

$$P_B = \frac{C \cdot P_e (1 - K v_r)}{2.37} \quad (\text{A1.6})$$

where:

- P_B = design reaction capacity, lb;
- P_e = predicted ultimate reaction capacity regression developed in **A1.4.6.3**, lb;
- v_r = combined COV for the regression from **A1.4.6.4**;
- K = factor for one-sided 95 % tolerance limit with 75 % confidence for a normal distribution based on the sample size for the regression being analyzed ($\sum n_i - J_r$). Values for this factor are given in **Appendix X5**, **Eq X5.20**, and **Table X5.3**. ($K = 1.952$ for $\sum n_i - J_r = 18$); and
- C = product of appropriate special use reduction factors from **Appendix X7**.

A1.4.6.6 The design regressions developed in **A1.4.6.5** shall be used to develop reaction capacities for bearing lengths between those tested. In test programs where the reaction capacity does not vary with joist depth, the single regression developed shall be applied to the full range of depths tested. For those test programs where reaction capacity is also found to be a function of joist depth, linear interpolation between regressions is permitted to determine the reaction capacity for joist depths between those tested. Extrapolation beyond the extreme bearing lengths and joist depths tested is not permitted.

A1.4.7 The design reaction capacities calculated in accordance with **A1.4.5** and **A1.4.6** are permitted to be adjusted for duration of load (DOL) in accordance with the section on Duration of Load Under Modification of Allowable Properties for Design Use in Practice **D245**.

NOTE A1.5—DOL adjustments are typically not applicable to buckling related reaction failures, but this is accounted for within the adjustment factor of 2.37 used in **Eq A1.3** and **Eq A1.6**.

A1.4.8 Compression Perpendicular to Grain—The compression perpendicular to grain strength of the flange material can limit reaction capacity determined in accordance with **A1.4.5.2** and **A1.4.6.5** and shall be analyzed separately. Wane and edge easing of flange material shall be considered in the analysis. DOL adjustments are not applicable to compression perpendicular to grain calculations.

NOTE A1.6—The compression perpendicular to grain strength of the supporting material may also limit reaction capacity. Consideration of support material's compressive strength as a factor limiting reaction capacity is required to be accounted for in design.

A1.4.9 Web Stiffeners—If a manufacturer wishes to establish reaction capacities with web stiffeners, testing shall follow the sampling, test methods, and data analysis detailed in Sections **A1.2**, **A1.3**, and **A1.4**. Data analysis shall be conducted independently of that for reaction capacity without web stiffeners. Web reinforcement material and installation (fastener, size, and quantity) shall be clearly identified and reinforcement permitted in application shall be equivalent to that which was qualified.

APPENDIXES

(Nonmandatory Information)

X1. PRODUCT EVALUATION CRITERIA FOR CODE COMPLIANCE

NOTE X1.1—This appendix is included in this specification as non-mandatory information, but is written in mandatory language to facilitate adoption by regulatory agencies and product certification bodies.

X1.1 Introduction

X1.1.1 The purpose of these criteria is to establish certification requirements for prefabricated wood I-joists, as defined in this specification, in accordance with national or local building codes.

NOTE X1.2—Examples of national building codes are International Building Code (IBC, **1**⁸), International Residential Code (IRC, **2**), and the National Building Code of Canada (NBCC, **3**). The IBC and IRC have since their inception in 2000 recognized I-joists as a group of approved construction materials. The recognition of I-joists under the NBCC is through applicable clauses of CSA O86 Engineering Design in Wood (**4**) and other NBCC provisions.

X1.2 Scope

X1.2.1 Prefabricated wood I-joists covered by these criteria are limited to applications specified in this specification. I-joist products used as rim boards, load bearing studs, shearwall,

fire-resistance-rated assemblies, or other applications not covered by this standard, are beyond the scope this appendix.

NOTE X1.3—Specification **D7672 (5)** provides procedures for evaluating structural capacities of I-joists used as rim board. Practice **E119 (6)** provides guidance for the evaluation of I-joists in fire-resistance-rated assemblies. In addition, code evaluation agencies may provide acceptance or evaluation criteria for applications not covered by this appendix. For example, ICC-ES **AC124 (7)** provides guidance for the evaluation of I-joist rim boards and ICC-ES **AC138 (8)** provides guidance for the evaluation of I-joists as load bearing studs in shearwall assemblies. Other acceptance or evaluation criteria established by code evaluation agencies are not precluded from consideration.

X1.3 Definitions

X1.3.1 I-joists covered by these criteria are defined in Section **3.1.1** of this specification. Additional definitions that are specific to these acceptance criteria are included in this section.

X1.3.2 Manufacturer—a firm or corporation producing a product that complies with this specification.

NOTE X1.4—A manufacturer is considered to be an organization as defined in ISO 9000:2005 (**9**).

X1.3.3 Manufacturer Plant Technical Director (MPTD)—a quality professional employed by the manufacturer who has

⁸ The boldface numbers in parentheses refer to the list of references at the end of this standard.

demonstrated competence in implementing a quality management system at the plant level.

X1.3.4 *Manufacturer Technical Expert (MTE)*—a quality professional employed by the manufacturer who provides specific knowledge of or expertise on products covered under these acceptance criteria and has demonstrated competence in managing and implementing a quality management system.

X1.3.5 *Monthly Quality Report*—a monthly quality report that contains a summary of product performance by grade or series with a comparison to requirements and a discussion of significant changes in raw materials and process.

X1.3.6 *Qualified Certification Agency*—an agency meeting the following requirements:

(a) has trained personnel to perform product certification in compliance with all applicable requirements specified in this standard,

(b) has procedures to be followed by its personnel in performance of the certification,

(c) has no financial interest in, or is not financially dependent upon, any single company manufacturing the product being certified,

(d) is not owned, operated, or controlled by any such company, and

(e) is accredited as complying with ISO/IEC 17065 by a recognized⁹ accreditation body for the certification of I-joists.

X1.3.7 *Qualified Inspection Agency*—an agency meeting the following requirements:

(a) has trained personnel to verify that the grading, measuring, species, construction, bonding, workmanship, and other characteristics of the products as determined by inspection are in compliance with all applicable requirements specified in this standard,

(b) has procedures to be followed by its personnel in performance of the inspection,

(c) has no financial interest in, or is not financially dependent upon, any single company manufacturing the product being inspected,

(d) is not owned, operated, or controlled by any such company, and

(e) is accredited as complying with ISO/IEC 17020 by a recognized⁹ accreditation body for the inspection of I-joists.

X1.3.8 *Qualified Testing Agency*—an agency meeting the following requirements:

(a) has access to the facilities and trained technical personnel to conduct testing on the characteristics of the products by sampling and testing in compliance with all applicable requirements specified in this standard,

(b) has procedures to be followed by its personnel in performance of the testing,

(c) has no financial interest in, or is not financially dependent upon, any single company manufacturing the product being tested,

(d) is not owned, operated, or controlled by any such company, and

(e) is accredited as complying with ISO/IEC 17025 by a recognized⁹ accreditation body for the tests required by this specification.

NOTE X1.5—The Qualified Certification Agency, Qualified Inspection Agency, and Qualified Testing Agency may be the same agency.

X1.3.9 *Quality Manual*—a document that establishes the minimum requirements for manufacturing practices, staff, facilities, equipment, and specific quality assurance processes, including inspection (in the U.S.) and/or certification (in Canada), by which the product is manufactured.

NOTE X1.6—The initial Quality Manual and all revisions shall be signed and dated by the TPTE and MTE.

X1.3.10 *Third-Party Auditor (TPA)*—a quality professional employed by the accredited inspection agency who has demonstrated competence in auditing a quality management system at the plant level.

X1.3.11 *Third-Party Technical Expert (TPTE)*—a quality professional employed by the accredited inspection agency who provides specific knowledge of or expertise on products covered under these acceptance criteria and has demonstrated competence in managing a quality audit system.

X1.4 Test and Analysis

X1.4.1 *General*—Sampling, conditioning, testing, and analysis of data shall be in accordance with this specification.

X1.4.2 *Specimen Sampling*—Sampling shall be performed by a qualified inspection, testing or certification agency, as defined in these criteria, or by the manufacturer under the supervision of a qualified inspection, testing, or certification agency. Sampling methods shall comply with Section 6 of this specification. The qualified agency supervising the sampling shall confirm that the samples are representative of the production in accordance with the requirements of the in-plant quality control manual.

X1.4.3 *Specimen Description*—Specimens shall be described in detail, including at a minimum, the I-joist depth; flange and web materials and dimensions; adhesives; and the manufacturing date and facility.

X1.4.4 *Testing Laboratories*—Testing shall be conducted by a qualified testing agency acceptable to the qualified certification agency. Testing shall be also permitted to be conducted at the manufacturer's testing facility, accredited or not, under the supervision of a qualified testing agency or certification agency. The manufacturer's testing facility is considered a subcontractor of the qualified testing agency or certification agency, and qualification tests conducted at a manufacturer's facility shall be under the control of, witnessed by, and approved by the qualified testing agency or certification agency as conforming to this specification.

X1.4.5 *Test Reports*—Test reports shall be issued or approved by the qualified testing agency or certification agency, and be limited to the products as tested.

NOTE X1.7—Practice E575 (10) provides guidance that may be considered for preparing reports from test data.

⁹ Recognized by the authority having jurisdiction (AHJ) or an agency verifying code compliance for the AHJ.

TABLE X1.1 Quality Assurance Levels I, II, III or IV Manufacturers

	Level I Manufacturer	Level II Manufacturer	Level III Manufacturer	Level IV Manufacturer
Quality Concept	Product Audit Through Industry Standards	Product Audit Through Industry Standards	ISO Compliant: Ready to Register ^G	ISO Registered ^C
Minimum Audit Frequency by TPA	12/year	6/year	4/year	3.2/year ^D
MTE and MPTD Education and Experience	Industry Experience	Sections X1.5.9.7 and X1.5.9.8	Sections X1.5.9.7 and X1.5.9.8	Sections X1.5.9.7 and X1.5.9.8
Intra-Company Quality Audits at Every Plant by MTE ^{A,B,H}	N/A	N/A	1/year	1/year
Plant Quality Audit by MPTD ^{F,H}	N/A	1/year	1/year	2/year
Review of QA Test Results ^I	1/year (MTE) Monthly (MPTD)	1/year (MTE) Monthly (MPTD)	2/year (MTE) Monthly (MPTD)	2/year (MTE) Monthly (MPTD)
Quality Manual	Yes	Yes	Yes	Yes
Documentation in accordance with ISO 9001-2000 (11)	No	No	Yes	Yes
Quality Plan ^E	No	Yes	Included in ISO Documentation	Included in ISO Documentation
Monthly QC Report by MPTD Required	Yes	Yes	Yes	Yes

^A Intra-company auditors can be from different plants. For companies with multiple plants, the MTE may designate a lead auditor that satisfies the education and experience requirements of an MTE. The MTE, however, still retains the primary responsibility for the Quality Management System.

^B External auditors shall be permitted to be contracted in cases where a company has only one plant.

^C To move from Level III to Level IV, successful documentation under these acceptance criteria for a minimum of two years is required in addition to ISO 9001 certification. Additionally, an on-site joint audit with third-party auditor and the qualified certification agency participation is required. Registration shall be conducted by an ISO 9001 agency registered by a registrar accredited by an International Accreditation Forum (IAF) member accreditor or an ISO 9000 registrar accredited by an IAF member accreditor.

^D Successful documentation and ISO registration for a minimum of two years are required for a move from three audits to two audits per year by the qualified inspection agency. Additionally, an on-site joint audit with third-party auditor and the qualified certification agency participation is required.

^E A Quality Plan provides information beyond the Quality Manual and shall be verified in accordance with Section **X1.5.4.5**. It shall include revision-controlled documents, retrievable records and procedures defining the following: (a) Product identification and traceability from raw materials to finished goods. (b) Corrective and preventative action process that can track/trend incidents of nonconforming product from identification through root cause analysis to resolution and closure. (c) Internal audit process to ensure that the procedures are being followed.

^F The MPTD shall audit each element of the Quality Plan (Level II) or Quality Management System (Levels III and IV).

^G Requires review of documentation by the qualified inspection agency and the manufacturer.

^H The intra-company quality audit by MTE and plant quality audit by the MPTD are conducted separately.

^I The MTE shall review QA test results in accordance with 10.6. See Sections **X1.3.4** and **X1.5.4.3** for MPTD requirements.

X1.5 Quality Control

X1.5.1 Quality control shall comply with Sections **8**, **9** and **10** of this specification at each manufacturing facility. The products shall be manufactured under a quality control program with inspections by a qualified inspection agency acceptable to the qualified certification agency. The inspection frequency shall be established by the qualified certification agency based on the quality level of the manufacturer, as specified in this section.

X1.5.2 Quality assurance levels for a manufacturer shall be established using a documented quality management system. Level I requirements noted in **Table X1.1** are set to coincide with the historical engineered wood industry practices.

X1.5.3 Quality system documentation complying with Sections **9** and **10** of this specification shall be submitted to and approved by the qualified certification agency for each facility manufacturing or labeling products that are recognized under these criteria.

X1.5.4 Quality Management System Requirements:

X1.5.4.1 The manufacturer shall establish and implement a quality management system that is fully documented in accordance with the requirements of **Table X1.1**. The documented quality management system shall describe the manufacturer's procedures and quality activities for ensuring that the products meet the specified requirements.

X1.5.4.2 The manufacturer, in concert with the qualified inspection agency, shall prepare and submit to the qualified certification agency its documented quality manual, including a cross-reference matrix to the quality management system.

X1.5.4.3 The MPTD shall submit a monthly quality report to the TPTE and MTE.

X1.5.4.4 The submitted quality management system shall be assigned a Level I, II, III, or IV.

X1.5.4.5 For Levels II, III, and IV, the TPA shall verify conformity to the quality plan at each audit. For Levels III and IV, a senior-level TPA appointed by the TPTE shall audit the plant together with the TPA once each year.

X1.5.4.6 Follow-up Inspections—The manufacturer shall obtain the services of a qualified inspection agency to conduct inspections of the fabrication facility in accordance with the minimum inspection frequency specified in **Table X1.1**.

X1.5.5 Audit by Qualified Certification Agency—Prior to advancement to Level IV, the manufacturer is required to undergo an on-site assessment by the qualified certification agency. This audit will be conducted jointly with the qualified inspection agency. The purpose of this joint audit is to determine the manufacturer's compliance with the documented quality management system, and to assess the inspection procedures of the inspection agency. After the audit frequency has been established by the qualified certification agency, any reductions in audit frequency by the third party (i.e., promotion from 3 to 2 audits/year) shall require an additional joint audit and appropriate documentation that the third-party certification or inspection agency has reviewed and approved the revised quality management system. Documentation shall be retained on file by the qualified certification or inspection agency. The qualified certification agency shall approve any ISO and qualified inspection agency combination inspections.

X1.5.6 Prior to advancement to Levels II or III, the manufacturer is required to undergo an assessment by the TPTE. The purpose of the assessment is to determine if the manufacturer's quality system meets the minimum requirements of the proposed Quality Assurance Level in **Table X1.1**. Documentation of the assessment shall be retained on file by the qualified certification or inspection agency.

X1.5.7 Manufacturer Technical Expert (MTE) Responsibilities—The manufacturer shall appoint an MTE that reports directly to the highest level of authority within the business or operating unit of the organization. The MTE shall be capable of providing leadership within the quality organization in the following areas:

- (a) Development of organizational structure.
- (b) Formulation of quality policies and procedures.
- (c) Establishment of quality performance goals.
- (d) Implementation of quality control tools and process control limits.
- (e) Statistical analysis and qualitative assessment of process and product performance.
- (f) Supplier assessment, certification, feedback and improvement.
- (g) Follow-up on customer feedback or field complaints.
- (h) Establish training and development programs for MPTD and other associates.
- (i) Maintain the manufacturer's documented quality system.
- (j) Monitor the effective implementation of the manufacturer's documented quality system.
- (k) Assure that periodic internal audits are conducted and documented, and that corrective actions are implemented.
- (l) Assure that annual management reviews are conducted and documented to assure the adequacy and effectiveness of the quality system. Management reviews shall include a summary and a documented plan of action for improvement.
- (m) Be familiar with and demonstrate knowledge of codes and standards as applicable to the quality assurance program.

- (n) Be an employee of the manufacturer who reports quality information and decisions directly to the highest level of authority within the business or operating unit of the organization.

X1.5.8 Manufacturer Plant Technical Director (MPTD) Responsibilities—The manufacturer shall appoint an MPTD at each production facility who shall:

- (a) Understand the organizational structure.
- (b) Implement the quality policies and procedures at the plant level.
- (c) Monitor and report the plant quality performance to the MTE.
- (d) Apply quality control tools and process control limits at the plant level.
- (e) Collect and report information to provide a qualitative assessment of process and product performance.
- (f) Collect information for supplier assessment, certification, feedback and improvement.
- (g) Investigate customer feedback or field complaints.
- (h) Participate in training and development programs.
- (i) Maintain the manufacturer's documented quality system at the plant level.
- (j) Be responsible for overall workmanship and for compliance to the documented procedures established by the manufacturer. Although inspections may be delegated to qualified personnel during the receipt and in-process stages of assembly, it is the responsibility of the MPTD to ensure that inspections are performed.
- (k) Be responsible for ensuring that incoming raw materials are properly identified and inspected for compliance with quality plans and specifications.
- (l) Be responsible for ensuring that the final QC test results can be traced back to the incoming raw materials, the quality assurance records and the responsible plant personnel.
- (m) Train and monitor performance of other personnel collecting process or product performance data.
- (n) Be an employee of the manufacturer that reports quality information directly to the MTE.

X1.5.9 Education and Experience:

X1.5.9.1 Education and Experience for MTE, MPTD, TPTE or TPA—MTE and MPTD shall be identified in the quality manual on the basis of appropriate education, training and experience such that the individuals are competent to take full charge of their responsibilities in accordance with the requirements noted in this section and also as required by the qualified inspection agency.

X1.5.9.2 Educational and experience requirements for qualified inspection agency personnel shall be in accordance with **Table X1.2**.

X1.5.9.3 The TPTE shall verify the education and experience, proof of professionalism and core knowledge of the MTE.

X1.5.9.4 The MTE shall verify the education and experience, proof of professionalism and core knowledge of the MPTD.

X1.5.9.5 Experience Waiver for Education—If an individual has completed a degree from an accredited college, university or technical school or certification by the American Society for

TABLE X1.2 Educational and Experience Requirements for Qualified Inspection Agency Personnel

Quality Level ^A	Level I	Level II	Level III	Level IV
Third-Party Accreditation	Qualified Inspection Agency	Qualified Inspection Agency	Qualified Inspection Agency	Qualified Inspection Agency ^B
TPTE Education and Experience	Industry Experience	Section X1.5.9.9	Section X1.5.9.9	Section X1.5.9.9
TPA Education and Experience	Industry Experience	Section X1.5.9.10	Section X1.5.9.10	Section X1.5.9.10
Third-Party Witness of Manufacturer's Manufacturing/Testing with TPA	Industry Experience, Able to Verify Compliance to Appropriate ASTM Standards	Same as Level I	Same as Level I	Same as Level I

^A See Table X1.1 for quality system elements.

^B The organization that ISO registers the manufacturer (i.e., separate organization) shall be either: a) ISO 9001 registered by a registrar accredited by an IAF member accreditor or b) ISO 9000 registrar accredited by an IAF member accreditor.

Quality (ASQ), part of the experience requirement shall be permitted to be waived as follows:

(a) Diploma from technical or trade school or advanced degree from non-related field – one year waived.

(b) Associate degree in Forest & Wood Sciences, Engineering or a related field – two years waived.

(c) ASQ Certified Quality Improvement Associate, Quality Engineer, Reliability Engineer, Six Sigma Black Belt, or Quality Technician – two years waived.

(d) ASQ Certified Quality Auditor – three years waived

(e) Bachelor's degree in Forest & Wood Sciences, Engineering, or a related field – four years waived.

(f) Master's or Doctorate degree in Forest & Wood Sciences, Engineering, or a related field – five years waived.

(g) ASQ Certified Quality Manager – five years waived.

(h) Professional Engineer registration – ten years waived.

X1.5.9.6 *Proof of Professionalism*—The MTE, MPTD, TPTE and TPA shall demonstrate proof of professionalism in one of three ways:

(a) Membership in ASQ, American Society of Civil Engineers (ASCE) or one other trade association applicable to the product produced.

(b) Registration as a Professional Engineer.

(c) The signatures of two persons – either an accredited inspection agency, ASQ or trade association member which can verify that the individual is a qualified practitioner of the quality sciences.

X1.5.9.7 *Manufacturer Technical Expert (MTE)*—The MTE shall meet the following minimum requirements:

(a) Ten years of on-the-job experience in one or more areas of Section X1.5.7 or X1.5.8 (see also Section X1.5.9.5). A minimum of five years of this experience shall be in a decision-making position. "Decision-making" is defined as the authority to define, execute or control projects/ processes and to be responsible for the outcome. This may or may not include management or supervisory positions. Current or previous certification by the ASQ as a Quality Auditor, Reliability Engineer, Software Quality Engineer, or Quality Engineer applies to job experience. On-the-job experience may be earned in accordance with the education requirements in Section X1.5.9.5.

(b) The MTE shall demonstrate an adequate knowledge of core subjects by satisfying education requirements of Sections X1.5.9.5(e) and X1.5.9.5(f), or a minimum of 25 Continuing Education Unit (CEU) or Recertification Unit (RU) credits (or equivalent hours of college education) from the list of topics in Section X1.5.9.7(d) or X1.5.9.10. At least 15 CEU or RU credits shall come from the core knowledge topics in Section X1.5.9.11(3). A one-year grace period, beginning on the date of the job appointment, is permitted to acquire the appropriate number of credits while working in the MTE position.

(c) The MTE shall demonstrate ongoing training by completing at least 4.5 RU credits every three years in accordance with Section X1.5.9.7(d).

NOTE X1.8—4.5 credits or 45 hours is equivalent to 15 hours per year, which is considered as a typical benchmark for a Professional Engineer.

(d) One RU credit is equivalent to one CEU credit or ten hours of participation. Recertification units can be earned in the following areas:

(1) Author or co-author of a published book or journal article.

(2) Reviewer of a published article or book.

(3) Participation in Standards Committees such as ASTM, ANSI..., etc.

(4) Participation in Trade Association Technical Committees or Conference Presentations.

(5) Participation in the qualified certification agency approved technical meetings.

(6) Being an instructor or student within the topics of Section X1.5.9.10.

X1.5.9.8 *Manufacturer Plant Technical Director (MPTD)*—The MPTD shall meet the following minimum requirements:

(a) Two years of on-the-job experience in one or more areas in Section X1.5.8 (see also Section X1.5.9.5). On-the-job experience may be earned in accordance with the education requirements in Section X1.5.9.5.

(b) The MPTD shall demonstrate an adequate knowledge of core subjects by satisfying education requirements of Section X1.5.9.5(b), X1.5.9.5(e), X1.5.9.5(f), or a minimum of 10 CEU or RU credits (or equivalent hours of college education) from the list of topics in Section X1.5.9.7(d) or X1.5.9.10.

At least 5 CEU or RU credits shall come from the core knowledge topics in Section **X1.5.9.11(3)**. One year of experience beyond the minimum of three years may be substituted for one CEU or RU. A maximum of 5 credits may be obtained through additional experience served under the guidance of a MTE. A one year grace period, beginning on the date of the job appointment, is permitted to acquire the appropriate number of credits while working in the MPTD position.

X1.5.9.9 Third-Party Technical Expert (TPTE)—The TPTE shall meet the following minimum requirements:

(a) Ten years of on-the-job experience in one or more areas related to Quality Assurance in the wood products industry (see Section **X1.5.9.5**). A minimum of five years of this experience shall be in a decision making position. "Decision-making" is defined as the authority to define, execute or control projects/processes and to be responsible for the outcome. This may or may not include management or supervisory positions. Current or previous certification by ASQ as a Quality Auditor, Reliability Engineer, Software Quality Engineer, or Quality Engineer applies to job experience. On-the-job experience may be earned in accordance with the education requirements in Section **X1.5.9.5**.

(b) The TPTE shall demonstrate an adequate knowledge of core subjects by satisfying education requirements of Section **X1.5.9.5(e)**, **X1.5.9.5(f)**, or a minimum of 25 CEU or RU credits (or equivalent hours of college education) from the list of topics in Section **X1.5.9.7(d)** or **X1.5.9.10**. At least 15 CEU or RU credits shall come from the core knowledge topics in Section **X1.5.9.11**. A one year grace period, beginning on the date of the job appointment, is permitted to acquire the appropriate number of credits while working in the TPTE position.

(c) The TPTE shall demonstrate ongoing training by completing at least 4.5 recertification units (RU) every three years in accordance with Section **X1.5.9.7(d)**.

NOTE X1.9—4.5 credits or 45 hours is equivalent to 15 hours per year, which was considered as a typical benchmark for a Professional Engineer.

X1.5.9.10 Third-Party Auditor (TPA)—The TPA shall meet the following minimum requirements:

(a) Three years of on-the-job experience in one or more areas related to Quality Assurance in the wood products industry (see Section **X1.5.9.5**). On-the-job experience may be earned in accordance with the education requirements in Section **X1.5.9.5**.

(b) The TPA shall demonstrate an adequate knowledge of core subjects by satisfying education requirements of Section **X1.5.9.5(b)**, **X1.5.9.5(e)**, **X1.5.9.5(f)**, or a minimum of 12 CEU or RU credits (or equivalent hours of college education) from the list of topics in Section **X1.5.9.7(d)** or **X1.5.9.10**. At least 6 CEU or RU credits shall come from the core knowledge topics in Section **X1.5.9.11(3)**. One year of experience beyond the minimum of three years may be substituted for one CEU or RU. A maximum of 6 credits may be obtained through additional experience served under the supervision of a TPTE. A one-year grace period, beginning on the date of the job appointment, is permitted to acquire the appropriate number of credits while working in the TPA position.

X1.5.9.11 Continuing Education Credits:

(1) The definition of one CEU credit is ten contact hours of participation in an organized continuing education / training experience under responsible, qualified direction and instruction. A contact hour is defined as a 60-minute clock hour of interaction between student and instructor.

(2) If CEU credits are not offered for a given course, then recertification (RU) credits can be calculated. The instructor shall record the hours of interaction between the student and instructor and assign one RU credit for every ten hours of participation in training.

(3) All ASQ certified courses are deemed acceptable for CEU credits. Courses, conferences and seminars offered within the industry are deemed acceptable, provided CEU credits are offered. The following list of topics is considered to be the core knowledge of the overall training program:

- (a) ICC Codes, Approvals, Evaluation and Building Official Acceptance
- (b) Role of the Third-Party Agency and Internal Auditing
- (c) North American Wood Design
- (d) Structural versus Serviceability Requirements
- (e) ASTM or ANSI Product Standards
- (f) Grading Procedures for Base Materials
- (g) ASTM or ANSI Testing Procedures, Failure Modes
- (h) Third-Party Witnessing and Report Requirements
- (i) Statistical Method Used to Assign Design Properties
- (j) Fastener Testing / Design
- (k) Preservative Treatment Effects on Product (if applicable)
- (l) Durability and Adhesive Test Requirements
- (m) Product Labeling and Traceability to Process
- (n) Business Corporate Quality Structure, Policies and Procedures
- (o) Business Quality Goals
- (p) Continuous Improvement and Innovation
- (q) Assessing Capability of Production Personnel
- (r) Procedures for Nonconforming Product or Base Materials
- (s) Application of ISO 9000 Standards to Quality Process
- (t) Auditing Procedures
- (u) Auditing Procedures
- (v) ISO/IEC 17065, 17025, or 17020 requirements
- (w) Document Control and Record Keeping within the Organization
- (x) Fire Testing / Performance
- (y) (Other topics as approved by Qualified Certification or Inspection Agency)

X1.6 Product Certification

X1.6.1 The product certification shall be issued by a qualified certification agency.

X1.6.2 The certified product shall be clearly and properly identified by product name, company name or logo, plant location or number, qualified inspection agency name or logo, qualified certification agency name or logo, and a means for establishing the date of manufacture.

NOTE X1.10—In many cases, the qualified certification agency also conducts plant inspections. Therefore, the labeling may only show the qualified certification agency.

X1.6.3 Product certification shall include a product evaluation report accessible by building officials and the general public. The report shall provide design properties determined in accordance with these criteria and the applicable building codes.

X2. COMMENTARY ON STANDARD SPECIFICATION FOR ESTABLISHING AND MONITORING STRUCTURAL CAPACITIES OF PREFABRICATED WOOD I-JOISTS

X2.1 *Scope*—Appendix X2 is intended to provide a general background and the underlying philosophies which led to the development of the standard in its present form. Other appendices explain specific technical aspects of various sections of the specification. The arrangement of this appendix follows the same sequence as the specification, but only certain sections here deal explicitly with sections of the specification.

X2.1.1 *General Index and Description of Major Features of the Standard*:

X2.1.1.1 *Design Considerations*—Some common considerations in application design of I-joists are given in Section 4.

X2.1.1.2 *Materials*—Materials used in fabrication of I-joists as defined in Section 3 are described in Section 5.

X2.1.1.3 *Qualification Required*—Section 6 of this specification specifies the analysis and minimum testing required for establishing structural capacities for new producers and new product lines. Qualification of components can be by other than the I-joist producer, provided the requirements of this specification are met as detailed in Section 10.

(1) *Shear Capacity Qualification*—Initial capacity may be established either by calculations or from test results, as specified in 6.2.

(2) *Moment Capacity Qualification*—Three options are detailed in 6.4: The capacity is based upon the flange tensile capacity which is obtained from tables of recognized values as defined or analysis of flange material tensile test results. The third option is capacity based on analysis of I-joist bending tests. When flanges contain end joints, they are qualified by analysis of tension test results and may limit moment capacity, when such capacity is determined from flange tensile capacity.

(3) *Stiffness Capacity Qualification*—Stiffness capacity is determined analytically using material elastic moduli in an equation which accounts for both bending and shear deformations. Stiffness is determined analytically regardless of procedure used to determine moment capacity. The equation used is confirmed by tests specified in 6.6.

X2.1.1.4 *Details*—Investigation of details which may affect structural capacities is required as part of the qualification specified in 6.7. This includes as a minimum, the bearing lengths and any reinforcing required to maintain shear capacity, and the effect of web-holes on shear capacity.

X2.1.1.5 *Design Values*—Design value and capacity are defined in Section 3. Establishment of design values is discussed in Section 7.

(1) *Design Values Monitored by Quality Assurance*—Useful definitions of quality assurance and quality control are given in Practice E699. Section 9 defines the intent of a required quality assurance program and outlines the minimum

content of the program. Section 10 defines requirements for component quality assurance accomplished by other than the I-joist producer.

X2.1.1.6 *Quality Control Testing Required*—In general, when a structural capacity is qualified by test, the same test will be required in the quality-control program. Quality control shear tests are always required even when qualification of shear capacity is by calculation.

(1) *Quality Control and Quality Assurance Required*—Both in-house and third-party inspections are required. Third-party inspections are performed by a qualified agency, meeting the requirements of Section 8 of this specification.

X2.1.1.7 *Periodic Reevaluation of Structural Capacities*—Section 11 of this specification specifies reevaluation of capacities. In general, the reevaluation is based on data developed in the quality-control testing program.

(1) *Intent of Reevaluation*—Reevaluation provides a formal confirmation of the quality-control program and a basis for adjusting the design values of the producer.

X2.1.1.8 *Supplier Evaluation for Empirical Moment Method*—The manufacturer may qualify with one supplier at the start to establish design moment capacities. Then at the depth with the highest tension stress (back calculated using the net section), conduct a minimum of 53 bending tests for each additional supplier. The fifth percentile with 75 % confidence must not be less than that of the original supplier. As an alternate, the manufacturer may qualify with one supplier at the start and conduct a minimum of 53 correlating tension tests with matched samples. Then conduct a minimum of 53 tension tests for each supplier. For each supplier used, the fifth percentile with 75 % confidence must not be less than that of the original correlating tension tests. Regardless of how the suppliers are qualified, they must be continuously monitored through quality control.

X2.2 Need for Standard and History of Development

X2.2.1 *Need for Standard*—The wood I-joist is a relatively complex composite member, comprised of a wide range of anisotropic materials which may themselves be composites. The range of sections possible and manufacturing processes which produce more or less continuous lengths, lead to members with possible applications ranging from direct replacement of 2 by 8 floor joists to roof spans of 60 ft or more. The first of these members appeared in the market in the early 1970s. By the early 1980s, a number of products, each with proprietary details and processes had appeared. Because no existing standard suitably addressed the variety of details and processes which evolved, a significant range of approaches to

the establishment of design values appeared. The inconsistencies in approaches, rapid growth in the I-joist industry, and requests from building code groups, made obvious the need for a standard general enough to encompass the product range.

X2.2.2 History of Development—In the fall of 1981, an interested group of producer’s representatives formed an *ad-hoc* committee to address the issue of a specification. This committee invited participation from various segments of the wood and adhesives industries and began work on a draft specification. By the end of 1985, a document considered complete in most essentials was agreed upon by a majority of the *ad-hoc* committee and transmitted to the building code groups as a recommended interim specification. The *ad-hoc* committee then agreed that a consensus specification was desired and requested ASTM Committee D07 to promulgate such a specification. Work began on this specification in the spring of 1986.

X2.3 General Philosophy—The intent of the specification is to provide a standard procedure for the evaluation of I-joists such that capacities for any producer will be consistent with the statistics of the producer’s strength distributions and thus will result in more or less uniform application performance. Therefore, the specification is as performance-based as was found practical. The qualification section was designed to be a minimum requirement consistent with sound structural engineering. The quality assurance and reevaluation sections are intended to rapidly correct any deficiencies in the qualification procedure. Additional discussion of qualification is in **X2.5**.

X2.4 Comments on Design Considerations—Section 4.1 of the specification refers to the load duration adjustments used for sawn lumber. This was judged appropriate as no evidence to the contrary has appeared for any common wood/adhesive composite. The committee considered this issue most carefully when specifying the time-to-failure (minimum 1 min) prescribed in the specification and concluded that the load rates implied were in keeping with currently acceptable ranges (for example, see Test Methods **D4761**). Moreover, adjustment to “normal duration” was considered to be a component of the “baseline” ratio of 2.9 explained in **X7.3**, as it is in factors used to obtain design values in other wood standards (for example, see Table 6 in Practice **D2915**). Assessing load duration factors for “unusual” components is beyond the scope of this specification.

X2.4.1 Repetitive Member Factors—With the recent introduction of ASTM guidelines for development of factors to quantify system effects for wood assemblies, a task group of this specification was formed to review the basis of the factors. The task group discussed the fact that historical repetitive member factors actually embodied a combination of load sharing and composite action effects. A review of the literature indicated that the 1.15 factor for lumber would actually compute to roughly two-third composite action effects and one-third load sharing effects. The literature noted that the amount of composite action is functionally related to the stiffness of the sheathing relative to the framing member and to the connection between them. Similarly, the literature noted that the amount of load sharing is functionally related to the

assembly configuration, to the stiffness variability of the framing members, and to the amount of correlation between the strength and stiffness of the framing members. The task group concluded that the amount of composite action in a prefabricated wood I-joist system would vary broadly across the large range of available I-joist depths. Thus, unless the committee was prepared to propose a series of factors that differed by joist depth, only a factor near unity could be safely applied across all depths. The task group also concluded that the stiffness variability in prefabricated I-joist framing members was significantly lower than that of sawn joists. In addition, data showed that the correlation between I-joist flexural stiffness and moment capacity within a joist series was not consistent and was often lower than the correlation reported for sawn joists. Thus, unless the committee was prepared to propose a series of factors that differed depending on the measured correlation for a given manufacturer, only a factor near unity could be safely applied across all joists in the marketplace.

X2.4.1.1 The final pieces of the decision process that led to revision of the factor were: (1) the acknowledgment that other changes in this specification were removing conservatism from various aspects of moment capacity calculation (up to 20 % increases), and (2) the desire to take another small step in the direction of simplicity for our designer customers (by removing the separate factor for repetitive member increases from all designs). The former led to the conclusion that the larger factor in the existing specification was too high and the latter leading to the proposal for a factor of unity. It must be noted that some members of the task group believed that the decision to completely remove the repetitive member factor for I-joists adds confusion rather than simplification, for the designer. Their argument was that experienced designers have come to expect a factor for repetitive member use, and its elimination would raise many questions. These task group members voiced their preference for either a constant factor slightly larger than unity (that is, 1.05) or the carry-over of factors consistent with the latest version of the National Design Specification for Wood Construction (that is, 1.04 and 1.07), with either option possibly being tied to applicability to joists up to some maximum depth. It is anticipated that the prefabricated wood I-joist industry will work toward coordinating the introduction of these changes into their literature and software. Because all current code provisions and industry design specifications permit factors higher than unity, it is anticipated that manufacturers will implement the changes into their design information gradually—and with clear guidance on how to apply their moment capacity values relative to repetitive member use.

X2.4.2 Adjustments for unusual moisture conditions may depend on the actual materials used in a given I-joist. Because of the variety of materials in use, any attempt to quantify such adjustments was considered beyond the scope of the specification.

X2.4.3 Generally, it is expected that I-joists will be produced from material which is at moisture content approximating that of “dry use” conditions. For this reason, adjustment of test results is not specified. The reduction factors explained in

Appendix X7 makes allowance for some strength loss which might be associated with temporary jobsite wetting.

X2.5 Comments on Qualification

X2.5.1 Qualification Test Sampling—The strength of an I-joist is strongly dependent on the quality of the material used. This must be expected to vary from time to time, even in material from the same supply sources. Production process variables may also change with time. For this reason, it was not considered possible to specify a meaningful sampling scheme and it is assumed that the quality assurance program will, with time, define fluctuations due to material and process variables. It is desirable to conduct preliminary tests to aid in the selection of representative specimens. A new producer is advised to give due consideration to these issues when selecting qualification samples.

X2.5.2 Evaluation of Test Results—In the case of shear strength, the analyses presented help justify the statistically minimal qualification test sample required. Detailed discussion and examples of this procedure are given in **Appendix X5**.

X2.5.3 Moment Capacity Qualification for the Analytical—It is recognized that the confirmation test procedure for the analytical moment capacity outlined in **6.4.2** may occasionally result in failures, even for material that has been assigned the proper moment capacity using the analytical method of **6.4.1**. Given that the analytical moment capacity design values are derived based upon a 5th percentile tolerance limit with 75 % tolerance for flange properties, there is some probability that an I-joist population that supports its assigned analytical moment capacity can experience a failure in a ten-piece confirmation test. The procedure outlined in **6.4.2.5** was adopted to provide a means to judge whether a confirmation test failure is due to a process problem or normal population variability. For simplicity, the committee elected to adopt the conservative procedure outlined in **6.4.2.5** for this purpose in lieu of a more statistically rigorous analysis. It is recognized that there is some probability that a population that supports its design value may also fail in the supplemental tests outlined in **6.4.2.5**.

X2.6 Discussion of Independent Inspection—The requirements of Section **8** and others, help lend credence to the concept of a performance-based specification. Moreover, the vast majority of prefabricated I-joists now being produced are proprietary, and the independent inspection is usually an integral part of building code acceptance of such products.

X2.7 Philosophy of In-House Quality-Assurance Requirements

X2.7.1 Any effective quality-control scheme must be devised with due consideration of production volume, the specific materials and manufacturing processes and their associated variabilities. Because of the wide range of materials, details, manufacturing processes, etc., possible in production of I-joists, detailed quality control procedures, including testing frequency and daily statistical analysis of data, must remain beyond the scope of this specification. Details of quality

control are the responsibility of the individual producer, qualified agency, and concerned regulatory organizations.

X2.7.2 In keeping with the concept of a performance-based specification, however, it is appropriate to specify the minimum general objectives and content of the quality-assurance program. More specifically, all major structural properties determined by qualification testing under the provisions of this specification must be monitored by the quality-control program to assure continuing acceptable performance.

X2.8 Philosophy of Periodic Reevaluation Requirements

X2.8.1 This section is intended to ensure that I-joist capacities are related to the actual performance of the members. The evaluation periods specified provide a formal basis for reporting and adjusting. In practice, it is expected that the quality-control program will provide a continuing evaluation in one form or another.

X2.8.2 In this procedure, the difficulty of selecting qualification specimens representative of long-term production is overcome.

X2.8.3 The procedure affords a check of the quality-control process without reference to the details of that process.

X2.8.4 A mechanism is provided for logical adjustment of design values based upon data which encompass the full range of material and manufacturing variables. As an example, qualification testing may, for some reason, indicate capacities which, when incorporated in an effective quality-control system, result in economically unacceptable reject rates; the manufacturer may then choose to include data from reject production and thus adjust values in keeping with some reject rate judged acceptable.

X2.8.5 Shear and bearing capacities are usually considered most sensitive to details of the manufacturing process. Therefore, a shorter initial evaluation period is specified for those test results. Bearing capacity, which is a function of bearing length, flange/web joint, reinforcing details and materials, is considered related to shear strength once testing has occurred over a sufficient time period to stabilize details relative to the full range of material variables. It should be noted that bearing length specified in Section **6** for shear capacity tests is not necessarily the minimum required. This is because the shear test not only demonstrates capacity, but also is considered the best test of product details and manufacturing processes. Therefore, it is desirable that the failure in a shear test usually initiates away from the bearing.

X2.9 Capacity and Design Value

X2.9.1 The descriptions of terms given in **3.1.1** are intended to encourage some exercise of judgment in assessing design values from the analyses detailed in the specification.

X2.9.2 A few of the factors which may influence a manufacturer to assess a design value less than capacity are:

X2.9.2.1 The qualification test specimens may not be truly representative. (See **X2.5.1**.)

X2.9.2.2 The quality of incoming material may vary from time to time or supplier to supplier.

X2.9.2.3 A high design value may result in an uneconomical reject rate in the quality-control program.

X2.9.2.4 The factors in X2.9.2.1 – X2.9.2.3, and other factors, are typically difficult to define without substantial time and experience in production.

X3. VOLUME EFFECTS IN PREFABRICATED WOOD I-JOISTS

X3.1 Scope

X3.1.1 The strength of prefabricated wood I-joists is related not only to material properties, but is also a function of member size, longitudinal stress distribution, and the strength and frequency of flange joints. In this specification, volume effects are accounted for either directly in the testing (that is, shear in accordance with 6.2 and moment in accordance with 6.4.3) or indirectly in the analysis (that is, moment in accordance with 6.4.1). The discussions in Appendix X3 provide background to the volume-related provisions of 6.4.1.

X3.1.2 During committee deliberations, it was questioned why prefabricated wood I-joists should account for length effects when competing products in the marketplace might not. A review of available standards and other information revealed that these effects are already included in glulam and structural composite lumber (in their volume factors) and in sawn lumber design (embedded in the Practice D1990 design value derivation procedures). The committee also noted that this issue is still being studied for trusses at North American research laboratories and is being discussed within the truss industry associations.

X3.2 Discussion of Flange Material Types

X3.2.1 Flange materials are divided into three types to accommodate differences in analysis and testing requirements for each type.

X3.2.2 For material type 6.4.1.3 (1), published lumber axial design values are used in the computation of moment capacity and no additional tension testing is needed to verify lumber strength. All standard ALS and CLS grades, including standard SPS-4 grades, fit in this category. Because input lumber lengths for this material type are “standard” (that is, 8 ft or longer), the only additional test verification of this flange material is the end joint testing in accordance with 6.5.1. The user is cautioned that SPS-4 design values may be based on a reference length of 96 in. rather than 144 in. if the product uses sawn lumber in lengths of less than 8 ft.

X3.2.3 For material type 6.4.1.3 (2), in which the manufacturer is using nonstandard axial design values, separate verification of tension values in accordance with 6.4.1.4 and 6.4.1.5 is required. As with 6.4.1.3 (3) material, end joints are evaluated in accordance with 6.5.1.

X3.2.4 For material type 6.4.1.3 (3), input lengths are not sufficient for separate evaluation of lumber strength. For this material, flange strength is evaluated by testing on a minimum 8-ft gage length with a representative number of end joints

present in the test specimens. As indicated in Note 9, SPS-4 provides users with several options for complying with the intent of this section.

X3.3 Discussion of Length Effect, Stress along the Length, and Joints

X3.3.1 The theoretical effects of length and stress variations along the length and the effects of joints in flange material are presented in Footnote 10.¹⁰ A brief discussion of these effects and their inclusion in this specification are included in the following sections.

X3.3.2 *Length Effect Factor Derivation*—Length effect is computed in a weak link analysis of the I-joist tension flange. Since flange tension strength is based on tests of relatively short lengths of flange material, it is appropriate to adjust strengths to typical application lengths. The factors in Table 1 are provided for the convenience of the user and are originally based on the relationship between Weibull shape parameter and tail-fit (Weibull) coefficient of variation. However, for ease of use, the table has been converted by the committee to normal COVs based on the distribution of full data sets. For simplicity, the tail-fit COV is assumed to be 70 % of the full distribution COV. This judgment is slightly conservative for most of the very large data sets representing common flange materials (that is, lumber, SCL) examined by the committee. The assumed COVs for 6.4.1.2 (1) lumber products are typical ranges of values. The committee chose to omit provisions that would permit the user to tail-fit specific data sets to generate alternate exponents for the length effect equation due to concerns related to unrealistically low COVs that could be generated in this manner. It was also determined to utilize the higher COV attained from either the tensile strength of the flange or that of the end joints. In some cases, this would require the COV of the flange to be utilized when checking length effect adjustments for end joints. This approach was taken to account for the reduction that would be seen for the combined effects of the lumber stress distribution and finger joint stress distribution.

X3.3.3 *Length Effect Factor Design Application*—Length effect is computed in a weak link analysis. The length effect factor is intended to be applied only as an adjustment to the basic moment capacity value and not as an application-specific design adjustment. The factor is intended to be computed at a single span-to-depth ratio (18) and incorporated in the published design moment for each I-joist depth by the joist manufacturer. The rationale for this judgment follows. Stress in

¹⁰ Sharp, D. J., Suddarth, S. K., and Beaulieu, C., “Length Effect in Prefabricated Wood I-Joists,” *Forest Products Journal*, Vol 50, No. 5, 2000, pp. 29–42.

the I-joist section will vary along the length of the member with the changes in moment diagram. The I-joist application design will be based on the maximum moment in the member which will often occur at only one point, and elsewhere moments will be less. Relative to a member stressed by a constant moment full length, this effect results in expected increase in strength. It was the judgment of the committee that I-joist design moment resistance should be based on simple span and uniform load with a span length of 18 times the joist depth. This judgment included consideration of other arrangements of supports and loading configurations.

X3.3.4 Stress Distribution Adjustment Factor—As indicated in the discussion of **X3.2.3**, offsetting the decrease in strength due to length is the increase in strength due to nonuniform tensile stresses along the length of a flexural member (relative to constant tension full length). The judgment of the committee is that these effects can be computed at a reference condition of simple span and uniform load, and can be reasonably applied to the full range of design applications with negligible error. The factor of 1.15 is viewed as a reasonable value for this parameter.

X3.3.5 The inclusion of joints in the flange introduces an additional failure mode which will affect flange strength, depending on their spacing and relative strength. Footnote 10¹⁰ provides additional discussion on this topic. The effect of joints is incorporated into this specification in two ways:

(1) The definition of F_a requires that the minimum of flange material axial values or end joint tensile values form the basis of the design calculation. This definition accounts for approximately 95 % of the joint effect for standard lengths of lumber.

(2) The definition of flange material **6.4.1.2** (3) requires a minimum tension test gage length of 8 ft and additionally requires that qualification specimens contain the characteristic number of end joints. This definition raises the requirement for short-length flange materials to the same level as the other flange material types.

These techniques incorporate approximately 90 to 100 % of the joint effect into the analysis. Given the additional complexity of incorporating a calculation-based joint effect into the standard, it was the judgment of the committee that the additional conservatism of not including the web contribution was adequate to permit the standard to neglect the remaining fraction of joint effect for the limited number of cases for which it would apply. Users are cautioned that use of web contribution factors greater than unity or stress distribution adjustment factors greater than 1.15 violate this judgment and would require explicit consideration of joint effects.

X3.4 Discussion of Analysis Techniques and Assumptions—The techniques underlying these provisions are consistent with SCL and glulam volume analyses in their focus on the

2-parameter Weibull distribution as the default distribution form. The data analysis techniques were also chosen to be consistent with Specification **D5457** (LRFD) techniques, which use the 2P Weibull and also permit the option of tail-fitting to improve Weibull fits. Tail-fitting has been shown to result in excellent representation of practically all data sets of engineered wood products.

X3.5 I-Joist Section Analysis

X3.5.1 Since this specification was originally published in 1990 (this paragraph was written in March 2001), the most common method of assigning moment capacity has been the product of the flanges-only section modulus and the tensile stress allowed in the flange material. When compared to test data, it was often observed that this resulted in a somewhat conservative moment capacity. This conservatism was believed to be related to the strength contribution from the web or the bending stress variation across the depth of the flange, or both.

X3.5.2 The inclusion/exclusion of web contribution from the calculation has often been debated in this committee. When moment capacity was computed by a flexural calculation (that is, net flange section modulus), the inclusion of web contribution was viewed to be consistent with the engineering mechanics. However, when moment capacity is computed by a flange tension calculation, the additional inclusion of web contribution is not believed to be consistent from a mechanics perspective. For this reason, it was judged that the web contribution should not be included in the analysis. One additional, pragmatic reason for excluding the web contribution from the calculation is to eliminate opposition to this method based on the argument that full-depth web holes, permitted in application, cannot contribute to increases in moment capacity.

X3.5.3 The bending stress variation across the depth of the flange, implicitly included in prior versions of this specification in the “net flange section” calculation, has been eliminated. **Eq 6** computes moment capacity using the standard engineering formula for a tensile chord or flange.

X3.6 Nonuniform Stress Along the Length—The principles of weak-link theory provide not only for strength decreases for longer length members, but also for strength increases for members at a given length with nonuniform stresses along their length. The factor K_S can be used to calibrate a member under the stress profile of a flexural member subjected to any arbitrary load configuration to the same member subjected to constant tension along its entire length. For purposes of this analysis, the judgment of the committee was to choose a single constant value of K_S (of 1.15) for this factor. The value of 1.15 was computed in accordance with Footnote 7 and is within 3 % of the computed value in the range from 10 to 18 % COV.

X4. PREFABRICATED WOOD I-JOIST ADHESIVES

X4.1 General

X4.1.1 Selection of adhesive, qualification, and quality-control procedures must result in performance conforming to the overall intent of the specification. **Appendix X4** is intended to serve as a guide and reference for adhesives to be used in the fabrication of wood I-joists. The referenced standards and procedures should be judged for their applicability to the manufacturing process of a given producer.

X4.1.2 All adhesives used, whether in the assembly of joints (flange to flange, end joints, web to flange, or web to web joints) or in composite structural lumber flanges, must be certified as meeting Specification **D2559** or, in Canada, as meeting an appropriate standard from the CSA Standards for Wood Adhesives, O112 Series, stipulated in CSA O86, for the curing parameters and materials used.

X4.1.3 It should be noted that in Canada and in certain other jurisdictions, the use of melamine and melamine-urea adhesives is not allowed even though joints using these adhesives may meet the requirements of Specification **D2559**.

X4.2 Prefabricated I-joists have been successfully used for several decades. One key to their broad acceptance has been based on their ability to claim that their adhesives do not degrade performance—from structural, moisture durability, or heat durability perspectives. The structural and moisture durability aspects have long been addressed in Specification **D2559** and CSA Standards for Wood Adhesives, O112 Series.

X4.3 When qualifying an adhesive for use in wood I-joists, consideration should be given for the process and ultimate

end-use application. For example, adhesive qualification testing should reflect the minimum temperature to be used in the manufacturing process.

X4.3.1 Likewise, melamine-urea-based adhesives should not be used when the in-service conditions result in exposure to the combined effects of a moisture content in the wood in excess of 16 % and a temperature of 120°F or greater. These are examples showing how the adhesive manufacturer's recommendations can be helpful when evaluating a particular adhesive for qualification.

X4.4 Full-scale product testing is a requirement of the specification as part of the qualification and quality provisions. An evaluation of the adhesive performance in these tests is recommended and desired. Although the specific tests are for evaluating joist shear, they provide an excellent opportunity to judge the glue line performance.

X4.5 Shear tests may point out if there is a glue line failure. The results must be judged carefully though, since low strength may not be related to a poor glue line.

X4.6 To help with the evaluation, certain levels of wood failure have been used historically to indicate if a glue line performed to an acceptable level. Recognized adhesive performance limits are as follows:

X4.6.1 *Web to Flange Joints*—A wood failure value greater than 70 % should be present.

X4.6.2 *Web to Web Joint (if applicable)*—A wood failure value greater than 50 % should be present.

X5. EXPLANATIONS OF STATISTICS USED IN THE STANDARD AND A SAMPLE EVALUATION OF SHEAR CAPACITY

X5.1 Scope

X5.1.1 *Statistics Used in the Specification*—**Appendix X5** provides an explanation of certain terms used in the specification. It is not intended as a general statistical reference, but may be a useful guide for those users with limited statistical background. References are given for those wishing to pursue the subject more thoroughly.

X5.1.2 *Sample Evaluation of Shear Capacity*—Under prescribed conditions, **6.2** permits combining of shear test data from joists of different depths. The relationship between shear strength and depth implied in the analysis is not usual in the statistical sense since the depths are deterministic. The example provides justification for the procedure.

X5.1.2.1 *Reason for Shear Capacity Procedure*—Combining the data gives a better estimate of variability from the larger sample size. The ability to combine data from different depths is a significant benefit in a quality-control program.

X5.1.3 *Units*—In **Appendix X5**, English units are used exclusively. Conversion factors for SI and metric units are in **IEEE/ASTM SI 10**.

X5.3 Discussion of Terms

X5.3.1 Normal Distribution—In this standard, shear strength is assumed to follow a normal distribution.

X5.3.2 Other Distributions—This specification presumes distributional knowledge only of shear strength. Flange or bending strengths may be better fitted by the lognormal or Weibull distributions.

X5.3.3 Tolerance Limit—Statistical tolerance limit. The proportion of the data expected, with stated confidence, to be below (or above) a given value. For example, in the strength capacity evaluations, we are 75 % confident that no more than 5 % of the data will fall below the calculated value. Equations and a table for factors used to find normal distribution tolerance limits are given in this appendix and in Practice D2915.

X5.3.4 Nonparametric Analysis—Data of an unknown distributional form is said to be nonparametric. Tolerance limits for nonparametric data are defined and appropriate factors given in Practice D2915.

X5.3.5 Correlation—Correlation defines the relationship between variables. Degree of correlation is measured by the coefficient of determination and by the standard error of estimate.

X5.3.6 Regression—Regression analysis provides an estimate of the relationship between variables; in this specification, expressed by a linear equation.

X5.4 Example of Shear Capacity Analysis

X5.4.1 Nomenclature—This section uses the following nomenclature:

- P = ultimate shear for a test specimen,
- \bar{P}_i = mean ultimate shear for depth (d_i),
- n_i = number of tests at depth (d_i),
- S_i = standard deviation of ultimate for depth (d_i),
- v_i = coefficient of variation for depth (d_i),
- P_e = expected mean from regression analysis,
- J = number of depths included in regression analysis,
- $S_{\bar{P}_i}$ = standard deviation of means of all depths in the regression analysis, and
- $S_{\bar{P}_i, d_i}$ = standard error of the correlation.

X5.4.2 Other terms are defined where required.

X5.4.3 Check of Normal Distribution—Data for examples were provided by Trus Joist Corporation and are results of shear tests (conforming to 6.2) conducted during the period January 1984 through June 1985. The data is for sample purposes only and does not necessarily relate to current production or capacity. Tests were of joists with plywood webs and structural composite lumber flanges; web reinforcing was used at supports on depths of 18 and 20 in. The data is tabulated in Table X5.1.

X5.4.4 Calculations:

X5.4.4.1 Equations for computing the normal curve are given in X5.6. The two parameters necessary to define the normal curve are:

$$\bar{P}_i = \sum P/n_i \quad (\text{X5.1})$$

$$S_i = \sqrt{(\sum P^2 - n_i \bar{P}_i^2)/(n_i - 1)} \quad (\text{X5.2})$$

X5.4.4.2 The coefficient of variation is:

$$v_i = S_i/\bar{P}_i \quad (\text{X5.3})$$

X5.4.4.3 Eq X5.1 and Eq X5.2 (loads divided by 2 for shear) give the example statistics tabulated in Table X5.2.

X5.4.4.4 To check for normal distribution, the 11.875-in. data was used.

X5.4.4.5 A program which follows the procedures of X5.6 and X5.7 was used to fit the normal curve to the data. Two goodness-of-fit tests were computed: The Anderson-Darling statistic A = 0.209 and DMAX for Kolmogorov-Smirnov Test = 0.056. Both indicate a close fit. The data and fitted curve are plotted on Fig. X5.1 where visual inspection also confirms the use of the normal distribution. From Table X5.2, note that data from other depths has similar variability and data range from means is reasonably symmetrical, so we conclude that all the data sets are normally distributed.

X5.4.5 Correlation and Regression Analysis:

X5.4.5.1 The means of the data from Table X5.2 are used to compute the regression equation:

$$P_e = A + Bd_i = 72 + 238d_i \quad (\text{X5.4})$$

X5.4.5.2 The intercept and slope are:

$$A = \frac{\sum \bar{P}_i \sum d_i^2 - \sum d_i \sum d_i \bar{P}_i}{J \sum d_i^2 - (\sum d_i)^2} = 72 \quad (\text{X5.5})$$

$$B = \frac{J \sum d_i \bar{P}_i - \sum d_i \sum \bar{P}_i}{J \sum d_i^2 - (\sum d_i)^2} = 238 \quad (\text{X5.6})$$

X5.4.5.3 The standard error is:

$$S_{\bar{P}_i, d_i} = \sqrt{\frac{\sum \bar{P}_i^2 - A \sum \bar{P}_i - B \sum d_i \bar{P}_i}{J - 2}} = 50 \quad (\text{X5.7})$$

where summation is from $I = 1$ through J and $J = 8$, the number of depths.

X5.4.5.4 The coefficient of determination is:

$$r^2 = 1 - S_{\bar{P}_i, d_i}^2/S_{\bar{P}_i}^2 = 1 - (50)^2/(905)^2 = 0.997 \quad (\text{X5.8})$$

where $S_{\bar{P}_i}$ is the standard deviation of the mean shears from Table X5.2.

X5.4.5.5 To check the linear assumption at a lower probability, the 95 % tolerance with 75 % confidence is computed for each depth as follows:

$$P_{0.05} = \bar{P}_i - kS_i \quad (\text{X5.9})$$

where k depends on the sample size for each depth and is taken from Table X5.3 or Eq X5.20.

X5.4.5.6 Correlating the $P_{0.05}$ values and the depth again results in a coefficient of determination approaching unity. This is expected for reasonably uniform sample sizes and COV's and confirms the approach.

X5.4.5.7 The 95 % tolerance with 75 % confidence has the regression equation $P_{0.05} = 106 + 192d_i$. The equation and the tabulated values of Table X5.4 are plotted on Fig. X5.2, along with the mean values from Table X5.2 and the mean regression equation (Eq X5.4).

X5.4.6 Determination of Shear Capacity Values from Combined Data:

X5.4.6.1 In the procedure for combining data, what is really being done is “normalizing” all data to a constant mean value regardless of depth. The underlying implication is that strength difference from depth to depth is solely a function of the depth change and that such difference is reasonably described by a known constant which is defined as the slope (B) of the

FIG. X5.2 Correlation of Shear Strength and Depth

regression equation. Of course, this is an assumption and the actual assertion is that the best estimate of shear strength is the regression equation rather than the data.

X5.4.6.2 Another way of considering this procedure is that changing section geometry affects shear strength, but unit material and joint strengths, the influences of manufacturing tolerances, etc., are constant for any depth. Test data is being used here because it is not known how to characterize all the individual, but interactive, strength components of the joists, which would presumably allow performance of a calculation that would adequately predict all the failure modes that occur (see Appendix X6 for examples).

X5.4.6.3 The mathematics of the procedure are simplified by using only the data means in the correlation. In the qualification, it is important that the number of tests at each depth included be reasonably consistent.

X5.4.6.4 To demonstrate this process, select some depth (d_n) as a constant and calculate the expected mean P_n (letting the base depth $d_n = 10$ in.):

$$P_n = 72 + 238(10) = 2452 \quad (X5.10)$$

The data for all other depths is then normalized by multiplying by the ratio:

$$R = 2452/\bar{P}_i \quad (X5.11)$$

X5.4.6.5 In this process, the mean for all depths becomes 2452, but the COV for any depth remains unchanged. Multiplying the COV times P_n gives equivalent standard deviations for each depth as listed in Table X5.5. Notice that it is not necessary to actually normalize all the data of Table X5.1 and recompute the standard deviations; multiplying the expected

mean value from the regression equation by the known COV for the depth, gives identical results.

X5.4.6.6 Using Eq 3 from 6.2.12.3 provides an estimate of the standard deviation using all of the available data:

$$S = \sqrt{\frac{\sum [(n_i - 1)S_n^2]}{\sum n_i - J}} = 248 \quad (X5.12)$$

Where summation is from $i = 1$ to J and $J =$ number of depths; n_i is number of tests for depth i . S_n is the normalized or equivalent standard deviation.

X5.4.6.7 The normalized coefficient of variation becomes:

$$V = \frac{248}{2452} = 0.1013 \quad (X5.13)$$

Identical results are obtained by using (v_i) for (S_n) in Eq X5.12. The combined sample size: $N = 483$ and from Eq X5.20 for the combined sample, $k = 1.69$ (for $n = 483 - J = 475$).

X5.4.6.8 Computing the expected 95 % tolerance with 75 % confidence as a function of depth:

$$P_{0.05} = 72 + 238d_i - 1.69(0.1013) [72 + 238d_i] \quad (X5.14)$$

$$P_{0.05} = 60 + 197d_i$$

Compare this result to the regression equation computed through the 95 % tolerance values (Table X5.4) of the data. The difference is insignificant in this case; greater differences should be anticipated given smaller data sets. However, the important point here is that the slope is the same (192 versus 197).

X5.4.6.9 Eq X5.14 gives 95 % tolerance with 75 % confidence values to use in determining the capacity from the data of Table X5.1. That is, in the Eq 4 of 6.2.12.4:

$$(P_e - kvP_e) = 60 + 197d_i \quad (X5.15)$$

and capacity as a function of depth is:

$$P_s = \frac{(60 + 197d_i)}{2.37} = 25 + 83.1d_i \quad (X5.16)$$

X5.4.6.10 A great convenience of this procedure is the ability to combine data from different depths in a daily quality-control scheme. Because the capacity is based on the regression equation, substituting that equation (P_e), X5.4, for (P) in Eq X5.11, gives a ratio which can be applied to any test result to “adjust out” the effect of depth. The resulting relative number can then be compared to the expected mean (P_n) in whatever statistical procedure is used in quality control.

X5.4.7 Check Requirements of 6.2.11—Using the random number table from Schaum’s, ten data points were selected

TABLE X5.6 Ten Random Values from Each of Four Depths

	10 in.	14 in.	16 in.	20 in.
	2513	3333	4155	4465
	2270	2870	3615	4700
	2425	3178	4065	5023
	2300	3668	2990	5185
	1975	3348	4170	4323
	2583	3510	3220	4615
	2180	2885	4070	5035
	2120	3270	4055	5040
	2245	3490	4410	3855
	2775	3343	3550	5325
\bar{P}_i	2339	3290	3830	4757
S_i	238	257	462	453
v_i	10.2 %	7.8 %	12.1 %	9.5 %

from Table X5.1 for 10, 14, 16, and 20-in. depths; the resulting values are tabulated in Table X5.6. Basically, this is a simulation of the minimum testing required in 6.2. How valid this simulation is may be questioned since the data in Table X5.1 was collected over a long period and such minimum testing would probably come from a short production run. However, the following calculations show that the criteria of 6.2.11 (min $r^2 = 0.9$) should be easily met, at least when the linear relationship is valid and the data COV is around 10 %:

Correlation of the means:

$$P_c = -89 + 243d_i \quad (X5.17)$$

$$\text{Standard Error} = 29 \quad r^2 = 0.999$$

Normalizing to 10-in. depth ($P_n = 2341$) gives:

d_i	Equivalent Standard Deviation = S_n
10	239
14	183
16	283
20	222

Eq X5.12 $S = 235 \quad \text{COV} = 10.04 \%$

$$N = 40 \quad (N - J = 36) \quad (X5.18)$$

$$k = 1.849 \quad (\text{Table X4.3})$$

$$P_{0.05} = -89 + 243d - 0.1004(1.849)(-89 + 243d)$$

$$= -72 + 198d_i$$

$$P_s = -30 + 84d_i$$

which is not significantly different from the previous result.

X5.5 One-Sided Tolerance Limits for a Normal Distribution—A one-sided tolerance limit, *PTL*, is a value about which it may be said with confidence $1-\gamma$, that at least a proportion, $1-p$, of the population is greater than *PTL*. The formula is as follows:

$$PTL = \bar{X} - Ks \quad (X5.19)$$

where \bar{X} and s are the mean and standard deviation, respectively, calculated from the sample data. K depends upon sample size n , as well as percentile $100-p$ and confidence $1-\gamma$. K values are given in Table X5.3 or they may be calculated from the formula:

TABLE X5.7 Linear Transformations

NOTE 1— ϵ and μ are location parameters respectively for three parameter Lognormal and Weibull distributions. Setting these values at zero will provide two parameter fits.

Distribution	Y_i	T_i
Normal	X_i	Standard Normal Z for $F_n(X_i)$
Lognormal	$\text{Ln}(X_i - \epsilon)$	Standard Normal Z for $F_n(X_i)$
Weibull	$\text{Ln}(X_i - \mu)$	$\text{Ln}[-\text{Ln}\{1 - F_n(X_i)\}]$

$$K = \frac{Z_p g + \sqrt{Z_p^2 g^2 - [g^2 - Z_\gamma^2 / (2(n-1))](Z_p^2 - Z_\gamma^2 / n)}}{g^2 - Z_\gamma^2 / (2(n-1))} \quad (X5.20)$$

where:

$$g = (4n - 5)/(4n - 4), \text{ and}$$

$$Z_p \text{ and } Z_\gamma = \text{are calculated with the following formula:}$$

$$Z = T - (b_0 + b_1 T + b_2 T^2) / (1 + b_3 T + b_4 T^2 + b_5 T^3) \quad (X5.21)$$

where:

$$T = \sqrt{\text{Ln}(1 / Q^2)} \quad (Q = p \text{ for } Z_p \text{ and } Q = \gamma \text{ for } Z_\gamma)$$

- $b_0 = 2.515517$
- $b_1 = 0.802853$
- $b_2 = 0.010328$
- $b_3 = 1.432788$
- $b_4 = 0.189269$
- $b_5 = 0.001308$

NOTE X5.1— K values computed using Eq X5.20 are approximations (see Ref (15) in Practice D2915). For small values, the formula can seriously overestimate the K factors.

X5.6 Normal Curve Calculations

X5.6.1 Equations X4.21 and X4.22 calculate either Z or Q for the right half of the normal curve when one or the other are known. Because of symmetry, this half of the standard normal is sufficient to handle any normal curve situation in which areas under the curve and associated abscissa values are involved. From a data set of variables called X , the transformation to a corresponding Z is:

$$Z = (X - \bar{X}) / s \quad (X5.22)$$

where \bar{X} is the mean and s is the standard deviation of the data.

X5.6.2 The area shown as Q in Fig. X5.3, if Z is specified, is given by:

$$R = F(Z) \{ a_1 T - a_2 T^2 + a_3 T^3 - a_4 T^4 + a_5 T^5 \} \quad (X5.23)$$

where:

$$F(Z) = \left[1 / \sqrt{(2\pi)} \right] \text{Exp}(-Z^2/2),$$

- $T = 1 / (1 + 0.2316419|Z|),$
- $a_1 = 0.31938153$
- $a_2 = 0.356563782$
- $a_3 = 1.781477937$
- $a_4 = 1.821255978$
- $a_5 = 1.330274429$

Then $Q = R$ if $Z \geq 0$; $Q = 1 - R$ if $Z < 0$.

FIG. X5.3 Area (Q) Under Normal Curve

0.05	0.757	...
0.10	0.637	...

X5.7 Fitting Distribution Curves and Testing Fit Quality— These fitting procedures are based on the principle of using probability paper graduated for a particular cumulative frequency distribution so as to produce a straight line plot of the data if the distribution fits well. It is, however, no longer necessary to seek out such papers nor is it necessary to plot the data by hand. Desktop or laptop computers can readily transform the axis variables to linear ones which, in effect, create the same linearized space produced by the probability papers. Plotting will produce a straight line path of data points if the curve for which the axes are transformed is appropriate. Simple linear regression line fitting can be accomplished in this space which will yield estimates of the distribution parameters. Tests of goodness of fit can also be made.

X5.7.1 Plotting and Transformations:

X5.7.1.1 The fundamental data consists of a rank ordered set of n observations arranged in ascending order with the rank one datum being the lowest value and the rank n datum being the highest value. The individual data values are labelled X_i and their cumulative frequency position is given by:

$$F_n(X_i) = i/(n+1) \text{ or } = (i - 0.5)/n \quad (X5.24)$$

where i is the rank. The plot of $F_n(X_i)$ versus X_i is called the empirical cumulative distribution function or EDF. A typical EDF plot is shown in Fig. X5.4 where compression strength is X and cumulative frequency is $F_n(X)$.

X5.7.1.2 A proposed theoretical cumulative distribution can be superimposed on the EDF for visual comparison of fit quality, but it is often difficult to judge how well one curve path fits another. By linearly transforming both variables, it is easier to see whether the path of points is generally linear. Linear transforms of values $F_n(X_i)$ to values Y_i and values X_i to T_i are given in Table X5.8 for Normal, Lognormal, and Weibull distributions. Other transformations are given in X4.2.2. An approximation function for calculating standard normal Z values is given in Eq. X4.23. An approximation function for calculating $F(X) = P$ is given in Eq X5.23.

X5.7.1.3 A linear plot in a lognormal transformed space of the data displayed in Fig. X5.4 is shown in Fig. X5.5. The data points generally follow a straight path. The linear, least squares regression line:

$$Y = A + BT \quad (X5.25)$$

fitted to the data Y_i, T_i is also shown in Fig. X5.3. It is possible to associate distribution parameters with A and B and to proceed to calculate goodness of fit statistics in the original $F_n(X_i), X_i$ space. The values of the parameters of the three theoretical distributions, $F(X_i)$, are given in Table X5.9. In this case, the logmean is A and the logarithmic standard deviation is B .

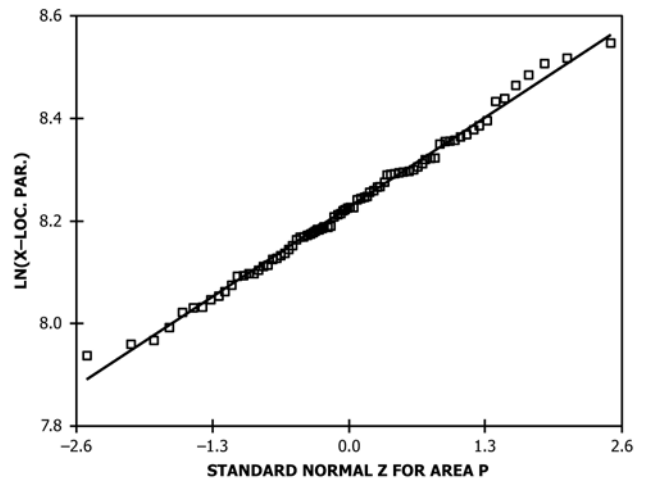

FIG. X5.5 Data Transformed to Linear Lognormal

X5.7.2 Goodness of Fit Tests:

X5.7.2.1 The correlation coefficient from the linear fit will yield some estimate of how well the data values group around the line, but the distortions of transformations are in this calculation. Measures of fit quality can better be made in the original $F(x)$ space in which the values $F(X_i)$ can be tested against their associated values $F_n(X_i)$. The simplest of these is the standard error of estimate, S , given by

$$S = \sqrt{\left\{ (1/n) \sum_i [F(X_i) - F_n(x_i)]^2 \right\}} \quad (X5.26)$$

X5.7.2.2 The values $F(X_i)$ can be calculated as $P(x)$ given by approximation Eq X5.23. S is used to compare the appropriateness of various distributions with regard to a single data set. The lowest value of S will indicate the tightest fit. If a

TABLE X5.9 Distribution Parameters from Linear Regression in Linearized Plotting Space

NOTE 1—The location parameters ϵ and μ are supplied externally to the fitting process to obtain three parameter Lognormal and Weibull fits. Determining best values for these parameters is discussed in X5.7.2.

$F(X)$	Mean	Standard Deviation	Shape	Scale
Normal	A	B		
Lognormal	A	B		
Weibull			1/B	Exp(A)

three-parameter lognormal or a Weibull is used, various trial values of the location parameter between zero and the lowest data value will usually yield one for which S is minimum.

X5.7.2.3 Once the best distribution is chosen in terms of minimum S , other statistics can be calculated for comparison with table values which will give a more general indication of fit quality. The Anderson Darling statistic, called A_2 , (X5.2.2) has been found to work well in judging goodness of fit of distributions to lumber mechanical properties data.

X5.7.2.4 The quantity $A = A^2(1 + 0.2 \sqrt{n})$ may be compared with the entries in Table X5.8 to test the hypothesis that the data come from the population represented by the fitted curve. The hypothesis is rejected, at the significance level α , if A exceeds the tabulated value. As the significance level, α , increases the test becomes more stringent requiring lower A values to prevent rejection.

X6. FAILURE CODING IN TESTS OF PREFABRICATED WOOD I-JOISTS

X6.1 *Scope*—Particularly in shear testing, a wide variety of failure modes is observed; many of these do not correspond with the appearance and mode of shear failures in other wood members. In fact, it can be argued that many of the observed modes are not shear failures at all. Nonetheless, most of these observed modes do influence the shear capacity and, with the exception of stiffness related web buckling, they are usually not separated in capacity evaluation. This appendix is offered primarily to avoid confusion due to the variety of failure modes often simply categorized as “shear failures.” A partial list of “shear” failure modes is given along with those of bending. One possible coding scheme and test-data sheet are suggested and sketches (Fig. X6.1) are included in explanation of codes.

X6.2 Example Coding System

X6.2.1 This coding system is designed to assist in describing failures of I-joists tested for product qualification, or quality-control purposes. Use of a data sheet like Fig. X6.2 may facilitate official documentation of test results. As failure trends develop, additional codings may be added to the list. Codes should be listed on the data sheet in the order that they were perceived to have contributed to failure, that is, major causes first. Use qualifiers in conjunction with codes (ZW with 6 in. of web-web joint involved). Evaluate glue line quality of joint failures by estimating percent wood failure at surfaces.

X6.2.2 Failure Codes Associated with Short-Span Shear Tests:

X6.2.2.1 *ZJ*—Failure line runs horizontally along bottom flange-web joint at end of the beam, then proceeds vertically along a web-web joint, then horizontally along the top flange-web joint toward the center span. Failure lines primarily follow glue joints.

X6.2.2.2 *ZW*—Same as *ZJ* except the web failure line does not involve a web-web joint, and usually the line runs nearer to 45° than vertical. Combinations of *ZJ* and *ZW* occur, with various amounts of the web-web joint involved.

X6.2.2.3 *IJ*—Similar to *Z* type failures, but with the horizontal flange-web joint failures extending both ways from the vertical web-web failure line.

X6.2.2.4 *FWJ*—Flange-web joint shear failure at the bottom or top joint.

X6.2.2.5 *WWJ*—Web-web joint vertical shear failure.

X6.2.2.6 *WHS*—Horizontal shear failure in web. (Mostly in plywood webs.)

X6.2.2.7 *WRS*—Rolling shear in web at web-flange joint. (For plywood webs.)

X6.2.2.8 *WC*—Web crushing, usually at end reaction with unstiffened ends.

X6.2.2.9 *WB*—Web buckle at end-reaction; usually without stiffeners.

X6.2.2.10 *FS*—Flange joint split at end reaction. Qualify with notes of minor, major, or measure and record length of split.

X6.2.2.11 *ER*—End rotation causes end bearing or *FS* failure. Additional lateral support probably required.

X6.2.2.12 *FF*—Occasionally, specimens fail in bending. Such failures should be excluded from shear data and one of the following codes can be added.

X6.2.3 Failure Codes Associated with Long-Span Bending Moment Tests:

X6.2.3.1 *FT*—Flange failure in tension. Record distance from center-line or end. Record type, size, and location of defect(s) involved. Evaluate if flange was on grade relative to visual specs.

X6.2.3.2 *FTJ*—Flange failure in tension at finger joint. Read percent of joint involved and percent of wood failure on failed surfaces (for example, (40/80)).

X6.2.3.3 *FC*—Flange failure in flexural compression. Commonly near load points.

X6.2.3.4 *FCB*—Flange failure in buckling. Usually due to inadequate lateral support.

X6.2.3.5 *SOG*—Slope-of-grain in flange. Either local, as around knots, or general. Measure general *SOG* and record if not in accordance with specification.

X6.2.4 Qualifier Codes:

X6.2.4.1 *BB*—Bad bond or no glue bond. Zero to thirty percent wood failure along glue joints.

The diagram illustrates the test setup for a full-scale I-beam. It shows a side view of the beam with dimensions: flange width b , gap between flanges, flange thickness t , web thickness d , total depth h , span length L_t , support spacing L_s , and load spacing L_m . Reaction points R_1 and R_2 are shown at the bottom. A load Pt is applied at the top center. A detail view on the left shows the flange-web junction with dimensions b , gap , d , t , and h . A detail view on the right shows the web with dimension h and gap . A dimension L_b is also indicated at the bottom left.

FAILURE CODES & DESCRIPTION:

FIG. X6.1 Example of Test Data Sheet

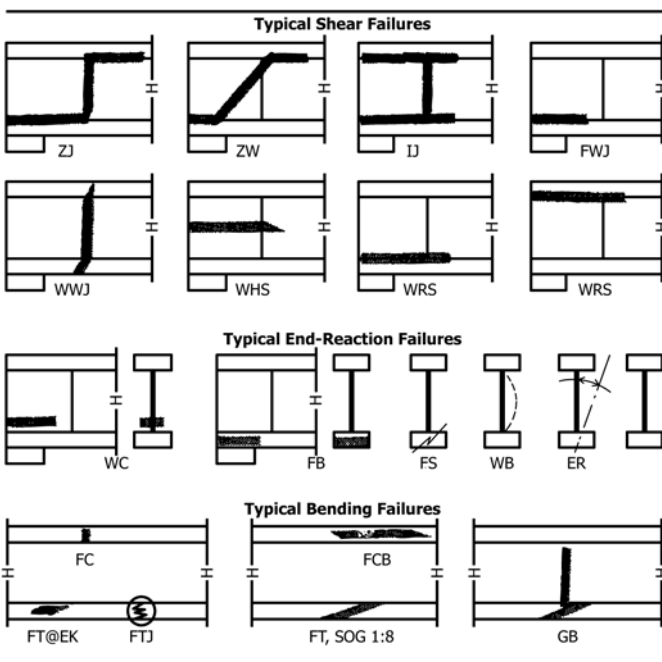

FIG. X6.2 Failure Codes for Full-Scale Tests

X6.2.4.2 *PB*—Poor bonding. Thirty to seventy percent wood failure along glue joints.

X6.2.4.3 *GB*—Good bonding. Seventy to one-hundred percent wood failure along glue joints.

X6.2.4.4 *GM*—Glue missing in joint.

X6.2.4.5 *NGT*—No glue transfer. Glue was spread, but did not transfer to mating surface. Usually due to inadequate assembly pressure, long open assembly time, or misfabrication. Measure length of joint involved.

X6.2.4.6 *PTT*—Prior to test. Relates to a process or a material defect observed before test.

X6.2.4.7 *OGM*—Off grade material. It is best to identify and record PTT.

X6.2.4.8 *% MC*—Percent moisture content. (For example, (15 % MC).)

X6.2.4.9 *NRP*—Not representative of production. It is best to identify and record PTT.

X6.2.4.10 *MAJ*—Major or primary cause or effect.

X6.2.4.11 *MIN*—Minor or secondary cause or effect.

X7. SHEAR CAPACITY REDUCTION FACTOR FOR PREFABRICATED WOOD I-JOISTS

X7.1 *Scope*—Eq 4 of 6.2.12.4 and Eq 5 of 6.2.12.5 include a possible factor for special use adjustments (C) and a divisor (2.37) to arrive at a capacity considered appropriate for structural members produced and used under the provisions of the specification. Appendix X7 provides an explanation of these factors.

X7.2 Explanation

X7.2.1 The denominator of the equations includes two factors considered appropriate to normal use of I-joists:

$$C_D = 0.62 \text{ to adjust data to normal (ten year) duration. (X7.1)}$$

X7.2.2 $C_B = 0.875$ allows for uncertainties considered usual to normal applications of I-joists. The principle concerns contained in this factor are normal construction tolerances which may reduce specified bearing length, minor damage to joist ends during installation, and some strength loss due to temporary wetting.

X7.3 An additional factor, F , to account for sample size and variability is derived as follows:

X7.3.1 It is a committee judgement that a suitable baseline is a ratio of 2.9 between the ultimate mean shear strength, \bar{P}_i , and the shear capacity, P_s , under the following standard conditions.

X7.3.1.1 The shear strength, P , is normally distributed.

X7.3.1.2 The standard distribution is based on a sample size of $N = 40$ and has a coefficient of variation, v , of 0.1. The shear capacity, P_s , as calculated by Eq 5 of 6.2.12.5, is to be the 5 % tolerance limit with 75 % confidence with reference to Table X5.6. The resulting factor, $K = 1.834$.

X7.3.1.3 The factor C in Eq 5 is temporarily set for this derivation at the product of C_D and $C_B = 0.5425$.

X7.3.2 Eq 5 is now expressed as $P_s = C\bar{P}_i(1 - Kv)/F$,

X7.3.2.1 Rearranging $\bar{P}_i/P_s = 2.9 = F/C(1 - Kv)$,

X7.3.2.2 Thus $F = 2.9C(1 - Kv) = (2.9)(0.5425)(1 - 0.1834) = 1.285$

for the above conditions.

X7.3.3 Combining F with the temporary C yields $F/C = 2.37$.

X7.3.3.1 Equation with the original C restored but no longer containing C_D or C_B becomes:

$$P_s = C(\bar{P}_i - Kv\bar{P}_i)/2.37 \quad (\text{X7.2})$$

X7.3.3.2 C now consists of other adjustment factors that may be necessary for satisfactory design. Two of these are:

(1) C_R = Effects of treatment, and

(2) C_M = Environmental effects such as elevated moisture or temperature.

X8. EXAMPLE OF REACTION CAPACITY ANALYSIS (Using the Default Qualification Procedure of A1.2.4.1)

INTRODUCTION

This example demonstrates an end reaction qualification where a manufacturer elects to use the Default qualification procedure. In this example, reaction capacity is found to vary with both joist depth and bearing length. Interpolation is used to define capacity within the bounds of the tested joist depths and bearing lengths.

X8.1 *Evaluation of Reaction Capacity*—Section A1.2.4.1 requires the extremes of bearing length and joist depth to be tested as independent groups. The data from each group is then reduced to a design value that can be interpolated to account for bearing lengths and joist depths that fall between the tested extremes.

X8.1.1 *Nomenclature*—This section uses the nomenclature defined in A1.4.5.

X8.1.2 Joist Description:

Depths available: 9.5 in., 11.875 in., 14 in., 16 in.

Flange: Laminated Veneer Lumber (LVL), 1.75 in. wide, 1.5 in. thick

Web: 5/8 in. OSB

X8.1.3 Compile Test Data—See Tables X8.1-X8.6.

X8.1.4 *Coefficient of Variation*—Determine the combined coefficient of variation for the data set using Eq A1.2.

$$v_d = \sqrt{\frac{\sum[(n_i - 1)v_i^2]}{\sum n_i - J_d}} \geq v_{\min}$$

where:

J_d = Four groups tested.

X8.1.4.1 Therefore:

$$v_d = \sqrt{\frac{0.4950}{40 - 4}} \geq 0.10 = 11.7\%$$

which is greater than the 10 % minimum, use $v_d = 11.7\%$

X8.1.5 *Reaction Capacity*—Determine the design reaction capacity for each group using Eq A1.3.

$$P_B = \frac{C \cdot P_i(1 - Kv_d)}{2.37}$$

X8.1.5.1 Therefore (note that the K factor is based on the individual sample size of 10 and $C = 1.0$ for this example):

9.5 in. Depth, 1.75 in. bearing: $P_B = 1.3429 \cdot (1 - 2.104 \cdot 0.117) / 2.37 = 1090$ lb
 9.5 in. Depth, 3.5 in. bearing: $P_B = 1.3679 \cdot (1 - 2.104 \cdot 0.117) / 2.37 = 1169$ lb
 16 in. Depth, 1.75 in. bearing: $P_B = 1.3845 \cdot (1 - 2.104 \cdot 0.117) / 2.37 = 1222$ lb
 16 in. Depth, 3.5 in. bearing: $P_B = 1.5333 \cdot (1 - 2.104 \cdot 0.117) / 2.37 = 1695$ lb

X8.1.5.2 In this example, linear interpolation is used to establish reaction capacities within the tested bounds of depth and bearing length in accordance with A1.4.5.3. Table X8.4 presents the reaction capacities for 100 % DOL.

X8.1.6 *Compression Perpendicular to Grain*—Calculate the reaction capacity based on flange compression perpendicular to grain (F_{c-perp}) in accordance with A1.4.8. Note that consideration of the supporting material allowable compression is accounted for during design and is excluded from this example.

X8.1.6.1 Analysis of reaction capacity with an adjustment for edge easing is shown in Table X8.6. A 1³/₄-in. wide LVL flange (plank orientation) is assumed with $F_{c-perp} = 425$ psi.

X8.1.7 *Design Reaction*—Select the smaller of the reaction capacity from Table X8.4, multiplied by a DOL adjustment if desired, and the flange compression capacity from Table X8.6 for each depth and bearing length combination.

X8.1.7.1 Linear interpolation of these design values is permitted between the bearing lengths shown. Manufacturers that choose to publish only minimum and maximum (1.75 in. and 3.5 in. for this example) may also linearly interpolate between these points.

X8.1.8 *Published Design Reactions*—Manufacturers may publish a design reaction for each DOL as shown in Table X8.5 or a single design reaction with notes to address DOL. If the manufacturer chooses to publish a single value and allow that value to be adjusted for duration of load, then a limit for the adjustment shall be provided to avoid exceeding the compression perpendicular-to-grain strength of the flange material.

X9. EXAMPLE OF REACTION CAPACITY ANALYSIS (Using the Regression-Based Qualification Procedure of A1.2.4.2)

INTRODUCTION

This example demonstrates an end reaction qualification where a manufacturer elects to use linear regression to define the relationship between bearing length and reaction capacity. In this example, reaction capacity is also found to vary with joist depth and interpolation is used to define capacity across joist depth at a given bearing length (A1.4.6.6).

X9.1 Evaluation of Reaction Capacity—A1.2.4.2 permits the combination of reaction test data for a joist depth tested at different bearing lengths using linear regression provided that a relationship can be established with a minimum r^2 of 0.9.

X9.1.1 Nomenclature—This section uses the nomenclature defined in A1.4.6.

X9.1.2 Joist Description:

Depths available: 9.5 in., 11.875 in., 14 in., 16 in.
Flange: Laminated Veneer Lumber (LVL), 1.75 in. wide, 1.5 in. thick
Web: $\frac{3}{8}$ in. OSB

X9.1.3 Compile Test Data—See Table X9.1, Table X9.2, and Fig. X9.1.

2.5	7	3411	185	5.42	2.5	7	3968	283	7.13
3.5	7	4154	254	6.12	3.5	7	4582	290	6.33

TABLE X9.3 Reaction Capacity (based on regression analysis)

Bearing Length, b_i (in.)	9.5 in. Reaction Capacity (lb)	16 in. Reaction Capacity (lb)
1.75	1016	1200
2.25	1126	1301
3.5	1401	1554

X9.1.3.1 With the resultant coefficient of determination $r^2 > 0.9$ for both data sets, regression analysis is allowed. The following coefficients are established in accordance with A1.4.6.3.

9.5 in. Depth: A = 1859 lb, B = 648 lb/in.
16 in. Depth: A = 2492 lb, B = 596 lb/in.

X9.1.4 Coefficient of Variation—Determine the combined coefficient for each regression using Eq A1.5:

$$v_r = \sqrt{\frac{\sum [(n_i - 1)v_i^2]}{\sum n_i - J_r}} \geq v_{\min}$$

where:

J_r = Three bearing lengths combined within each regression.

X9.1.4.1 Therefore:

$$9.5 \text{ in. Depth: } v_r = \sqrt{\frac{0.05915}{21 - 3}} \geq 0.10 = 5.73 \%$$

which is less than the 10 % minimum, use $v_{\min} = 10 \%$

$$16 \text{ in. Depth: } v_r = \sqrt{\frac{0.07030}{21 - 3}} \geq 0.10 = 6.25 \%$$

which is less than the 10 % minimum, use $v_{\min} = 10 \%$

X9.1.5 Reaction Capacity—Determine the design capacity for each regression using Eq A1.6. The calculated results based on the regression analysis are shown in Table X9.3.

$$P_B = \frac{C \cdot P_e (1 - K v_r)}{2.37}$$

X9.1.5.1 Therefore (note that the K factor is based on the combined sample size of $\sum n_i - J_r$ or 18 for each I-joist depth and C = 1.0 for this example):

$$9.5 \text{ in. Depth: } P_e = 1859 + 648(b); P_B = 1 \cdot (1859 + 648 \cdot (b)) \cdot (1 - 1.952 \cdot 0.10) / 2.37 = 631 + 220 \cdot (b)$$

$$16 \text{ in. Depth: } P_e = 2492 + 596(b); P_B = 1 \cdot (2492 + 596 \cdot (b)) \cdot (1 - 1.952 \cdot 0.10) / 2.37 = 846 + 202 \cdot (b)$$

X9.1.5.2 In this example, linear interpolation is used to establish reaction capacities for depths between 9.5 in. and 16

TABLE X9.4 Design Reactions

Bearing Length, b_i (in.)	Flange Compression Capacity ^{A,B} (lb)
1.75	1190
2.25	1530
3.5	2380

^AFlange Compression Capacity = Flange $F_{c-perp} \times (b_i) \times (\text{flange width} - 0.15)$.

^BCapacities may not be increased by DOL.

X9.1.6 *Compression Perpendicular to Grain*—Calculate the reaction capacity based on flange compression perpendicular to grain (F_{c-perp}) in accordance with A1.4.8. Note that consideration of the supporting material allowable compression is accounted for during design and is excluded from this example.

X9.1.6.1 Analysis of reaction capacity with an adjustment for edge easing is shown in Table X9.6. A 1¾-in. wide LVL flange (plank orientation) is assumed with $F_{c-perp} = 425$ psi.

X9.1.7 *Design Reaction*—Select the smaller of the reaction capacity from Table X9.5, multiplied by a DOL adjustment if desired, and the flange compression capacity from Table X9.6 for each depth and bearing length combination.

X9.1.7.1 Linear interpolation of these design values is permitted between the bearing lengths shown. Manufacturers that choose to publish only minimum and maximum (1.75 in. and 3.5 in. for this example) may also linearly interpolate between these points.

X9.1.8 *Published Design Reactions*—Manufacturers may publish a design reaction for each DOL as shown in Table X9.4 or a single design reaction with notes to address DOL. If the

in. for each bearing length in accordance with A1.4.6.6. Table X9.5 presents the reaction capacities for 100 % DOL.

manufacturer chooses to publish a single value and allow that value to be adjusted for duration of load, then a limit for the

adjustment shall be provided to avoid exceeding the compression perpendicular-to-grain strength of the flange material.
