National foreword

This British Standard is the UK implementation of EN 16424:2014.

The UK participation in its preparation was entrusted by Technical Committee B/508, Waste Management, to Subcommittee B/508/3, Characterization of waste.

A list of organizations represented on this subcommittee can be obtained on request to its secretary.

This publication does not purport to include all the necessary provisions of a contract. Users are responsible for its correct application.

English Version

Characterization of waste - Screening methods for the element composition by portable X-ray fluorescence instruments

Caractérisation des déchets - Méthode de dépistage pour la détermination de la composition élémentaire au moyen d'analyseurs portables de fluorescence X

Charakterisierung von Abfällen - Screening-Verfahren zur Bestimmung der elementaren Zusammensetzung mit tragbaren Röntgenfluoreszenzspektrometern

This European Standard was approved by CEN on 16 August 2014.

CEN members are bound to comply with the CEN/CENELEC Internal Regulations which stipulate the conditions for giving this European Standard the status of a national standard without any alteration. Up-to-date lists and bibliographical references concerning such national standards may be obtained on application to the CEN-CENELEC Management Centre or to any CEN member.

This European Standard exists in three official versions (English, French, German). A version in any other language made by translation under the responsibility of a CEN member into its own language and notified to the CEN-CENELEC Management Centre has the same status as the official versions.

CEN members are the national standards bodies of Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, Former Yugoslav Republic of Macedonia, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Norway, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, Switzerland, Turkey and United Kingdom.

Foreword

This document (EN 16424:2014) has been prepared by Technical Committee CEN/TC 292 “Characterization of waste”, the secretariat of which is held by NEN.

This European Standard shall be given the status of a national standard, either by publication of an identical text or by endorsement, at the latest by April 2015, and conflicting national standards shall be withdrawn at the latest by April 2015.

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. CEN [and/or CENELEC] shall not be held responsible for identifying any or all such patent rights.

X-ray fluorescence spectrometry (XRF) is a fast and reliable method for the determination of the total content of certain elements within different matrices. Quantitative analysis using XRF is described in EN 15309 [2]. For screening purposes, portable instruments are often used, especially when only the absence or presence of elements is under investigation or qualitative results with an indication of the concentration level are requested. This standard is applicable for on-site verification at landfills (see CEN/TR 16130 [4]) and it is an exemplification of EN 16123 [3].

According to the CEN-CENELEC Internal Regulations, the national standards organizations of the following countries are bound to implement this European Standard: Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, Former Yugoslav Republic of Macedonia, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Norway, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, Switzerland, Turkey and the United Kingdom.

Licensed copy: Lee Shau Kee Library, HKUST, Version correct as of 03/01/2015, (c) The British Standards Institution 2013 Licensed copy: Lee Shau Kee Library, HKUST, Version correct as of 03/01/2015, (c) The British Standards Institution 2013

1 Scope

This European Standard is dedicated to field portable X-ray fluorescence (XRF) equipment (hand-held or portable bench top) and specifies a screening method for the determination of the elemental composition of waste materials for on-site verification. Portable XRF spectrometers are used for a rapid and exploratory analysis of paste-like or solid materials. The absence or presence of specific elements is displayed qualitatively with an indication of the concentration level.

2 Normative references

The following documents, in whole or in part, are normatively referenced in this document and are indispensable for its application. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

EN 15002, *Characterization of waste — Preparation of test portions from the laboratory sample*

3 Terms and definitions

For the purposes of this document, the following terms and definitions apply.

3.1
field portable XRF spectrometer
XRF spectrometer for analyzing samples in the field, namely hand-held or portable bench top XRF spectrometers

3.2
hand-held XRF spectrometer
XRF spectrometer which can be used for in-situ analysis by direct probing or mounted on a stand

3.3
on-site verification
third level of inspection according to the Landfill Directive and the Landfill Decision to ensure that the waste accepted at a landfill is the same as described in the accompanying documents and that it is in accordance with the basic characterization and/or compliance testing

3.4
portable bench top spectrometer
compact bench top XRF spectrometer which can easily be carried into the field

3.5
screening
application of any analytical method for exploratory analysis

4 Principle

The sample can be measured directly or after a suitable sample preparation. In principle two different methods are used for probing the sample, either a pistol-like instrument is placed directly on the sample or a sufficient test portion is taken and put into a sample cup for measurement with the XRF instrument. The presence of a specific element is verified if a significant intensity for that element is measured. The intensities of the lines can be evaluated to indicate the concentration range.

Licensed copy: Lee Shau Kee Library, HKUST, Version correct as of 03/01/2015, (c) The British Standards Institution 2013

5 Safety remarks

The X-ray fluorescence spectrometers on the market are generally fully protected apparatus which are subjected to specific official approval and acceptance conditions. This means that the user is not exposed to radiation when operating the apparatus correctly. Nevertheless while measuring in the field, scattering radiation can be produced when probing directly on the sample. Providing a protective radiation shield around the sample when measuring avoids these risks.

The person responsible for managing or supervising the operation of X-ray equipment shall provide evidence of his knowledge of radiation protection according to national regulations.

Proper safety precautions shall be considered when conducting field XRF measurements. The operator should always be aware that X-rays are produced during measurements. The operator should never point the open source at anyone and be aware that X-rays can penetrate through light atomic mass matrices. Proper training regarding handling of XRF instruments is an obligation.

Take care when handling samples that may contain sharps or are of a dusty nature. Handling of samples should be performed with gloves and in the case of dusty materials with respiratory mask and gloves.

Take special precautions with samples from potentially hazardous waste. Avoid any contact with the skin and/or inhaling of dust.

6 Apparatus and equipment

6.1 X-ray fluorescence spectrometer

The X-ray fluorescence spectrometer shall comply with European and national regulations relevant to radiation protection.

The X-ray fluorescence spectrometer shall be able to analyse the relevant elements. The following types of X-ray fluorescence spectrometers are applicable:

— energy dispersive X-ray fluorescence spectrometer (EDXRF) which gains the dispersion of the emitted X-ray fluorescence radiation by an energy dispersive detector;

— wavelength dispersive X-ray fluorescence spectrometer (WDXRF) which gains the dispersion of the emitted X-ray fluorescence radiation by diffraction by a crystal.

For screening analysis generally EDXRF instruments are applied.

Portable spectrometers comprise mainly the following components:

— a primary X-ray source, a miniaturised X-ray tube with a low voltage generator;

— a detector unit including electronic equipment;

— a power supply including rechargeable batteries;

— a radiation shield according to safety regulations;

— optional source modifiers to modify the shape or intensity of the source spectrum or the beam shape e.g. primary source filters.

Portable spectrometers are mostly hand-held instruments which may be mounted on a stand. Alternatively small bench top systems are available which are equipped with a sample holder. In general, the weight of portable instruments should be below 10 kg and the size should be less than 500 mm wide, 500 mm deep and 200 mm high.

Licensed copy: Lee Shau Kee Library, HKUST, Version correct as of 03/01/2015, (c) The British Standards Institution 2013

The detector unit is different for wavelength dispersive (WDXRF) and for energy dispersive (EDXRF) spectrometers. WDXRF spectrometers take advantage of the dispersion of the emitted radiation by scattering by a crystal. EDXRF spectrometers are using an energy dispersive detector. The detector current pulses, a measure for the energy of the incoming X-rays, are segregated into channels according to energy using a multi-channel analyser (MCA).

6.2 Direct measurement using a hand-held instrumentation in direct contact with the sample

When using a pistol-like instrument, direct probing of the sample is possible (see Figure A.1 and Figure A.2). To avoid uncertainties due to different measurement geometry such as distance to sample, angle between sample and incident beam, the measuring window of the instrument should be in close contact to the sample.

6.3 Hand-held instrumentation mounted on a stand using sample cups filled with the sample

For practical reasons or to improve the accuracy of the results due to different measurement geometries, hand-held instruments may be mounted in a stand to operate with a well-defined geometry. Sample cups containing the material under investigation are placed into the instrument at a fixed position (see Figure A.3 and Figure A.4).

6.4 Portable bench top XRF instrument

Portable bench top XRF systems equipped with a sample holder for positioning sample cups may show improved repeatability of the results compared to hand-held instruments. A mounted shield against X-ray radiation provides a higher safety protection (see Figure A.5).

6.5 Spoon, stamp and/or hammer

Tool to prepare (e.g. compress, flatten) the sample prior to the measurement.

6.6 Mortar and pestle

Tool to grind the sample, if required.

6.7 Thin-film support

Select a thin film support that provides maximum transmittance and is resistant to the components in the sample (e.g. Mylar, polypropylene). Preferably samples are analysed using the same film that was previously used for calibration. The selected thin film shall be contaminant-free with respect to the elements of interest.

6.8 Sample cups

Select a sample cup suitable to be positioned in the applied XRF system. The sample cup needs to be assembled using an appropriate thin film support.

7 Calibration

7.1 General

The calibration strategy is comparable for energy dispersive and wavelength dispersive technique.

When using energy dispersive instruments, deconvolution of the spectra is needed when analysing complex samples with overlapping lines. Usually XRF instruments are supplied with a specific software module for that purpose.

Licensed copy: Lee Shau Kee Library, HKUST, Version correct as of 03/01/2015, (c) The British Standards Institution 2013

The calibration procedures for screening purposes are dependent on the analytical software package of the instrument. Most of them use a programme which contain calibration curves previously set-up; often by the manufacturer. In most cases the user can also set-up calibration programmes or improve the existing ones.

7.2 Interferences

Interferences in X-ray fluorescence spectrometry consists of spectral line overlaps, matrix effects, spectral artefacts and particle size or mineralogical effects.

Spectral line overlaps occur when an analytical line cannot be resolved from the line of a different element. In general, these interferences are removed using the algorithms provided with the software. However, due to the complexity of waste samples optimal matrix calibration is in most cases not affordable for screening experiments. Therefore the user shall be aware of those characteristic interferences which may occur in waste samples under investigation. A list of characteristic interferences is given in Annex B.

Matrix effects occur when the X-ray fluorescence radiation from the analyte element is absorbed or enhanced by other elements in the sample before it reaches the detector.

Spectral artefacts (e.g. escape peaks, sum peaks, pulse pile up lines, dead time, bremsstrahlung correction) are accounted for by the provided software. Spectral artefacts differ for energy-dispersive and wavelength-dispersive XRF.

7.3 Calibration procedure

Calibration involves the measurement of emitted intensities of characteristic lines for specimens of known composition. The basic formula implies a linear relationship between the intensity and the concentration.

$$C_i = a_{i,0} + a_{i,1} \times I_i \quad (1)$$

where

C_i is the concentration of the element of interest;

$a_{i,0}$ is the offset of the calibration curve;

$a_{i,1}$ is the slope of the calibration curve;

I_i is the net intensity of the element of interest.

Different calibration procedures can be applied for the determination of the element concentration according to EN 15309 [2].

It is a necessity to select a calibration programme which is able to handle the sample matrices under investigation, meaning performing the deconvolution, the interelement corrections and the calculation of the element concentration in a proper way. This can be done by using a universal or matrix-specific calibration programme. It is the task of the XRF user to validate the system with representative reference samples.

7.4 Validation of the calibration

The calibration shall fit with the concentration values to be verified by the investigation. The calibration protocol should be able to verify the lowest (highest) values within the calibration range.

The available precalibrated analytical method shall be validated using reference materials with a similar composition as the unknown samples. Based on the obtained results an estimation of the uncertainty range for each analyte can be defined. The reference sample can consist of:

a) certified reference materials with matrices similar to that of the unknown sample;

Licensed copy: Lee Shau Kee Library, HKUST, Version correct as of 03/01/2015, (c) The British Standards Institution 2013

b) in-house made reference materials with matrices similar to that of the unknown sample;

c) synthetic standard samples, made by weighing the appropriate amount of each pure reagent;

d) site specific or batch specific samples, similar to the matrix of the unknown sample;

e) standard addition method or spiked samples may also be used to create standards for which appropriate reference materials are not available for an element of interest; the matrix material shall match that of the unknown sample.

The element concentrations of these reference samples shall be known, by certification, or by determination with another analytical technique.

The reference materials shall be analysed under the same analytical conditions as the unknown sample, meaning the same sample preparation (pellet, powder, etc.), the same analytical measurement method, etc.

If no reference materials with a comparable matrix as the unknown sample are available, only a qualitative analysis with indicative concentration values can be performed. A method can be defined as (semi)-quantitative when the uncertainty ranges can be defined.

8 Screening strategy

The operational steps for screening experiments are defined below and presented in the flowchart in Figure 1.

Step 1: Define analytical task. Identify the elements including the corresponding concentration values to be verified and/or decision values.

Elements of interest are listed in the European and national legislation. In case of landfills the European Landfill Directive mentions these elements as relevant: As, Ba, Cd, Cr, Cu, Hg, Mo, Ni, Pb, Sb, Se, Zn, (Cl).

Step 2: Perform the necessary sample preparation.

The sample preparation technique depends on the selected measurement procedure. See Clause 9.

Step 3: Select a suitable (matrix specific) XRF calibration programme (see Clause 7).

Step 4: Perform the replicate measurements (see Clause 10) and calculate the relative repeatability standard deviation (V_r) of the replicates.

Step 5: Is V_r of the replicates sufficiently low? If no, go to step 6; if yes, continue with Step 7.

When evaluating the resulting concentration values, the V_r in relation with the concentrations to be verified and/or decision values shall be considered.

Usually a V_r of less than 30 % is a proper criterion to decide between acceptable or not acceptable results.

Step 6: If V_r is not sufficiently low, the sample preparation needs to be improved. Check, if the results are getting acceptable by repeated sample preparation. If yes, repeat from step 2. If no, go to Step 12.

Improved sample preparation can include homogenization, and drying.

Step 7: Is an indication of the concentration level required? If no, go to Step 8; if yes, continue with Step 10.

Step 8: Compare the mean of the results with the limit of detection (LOD) (see 12.2).

Step 9: Indicate the absence or presence of the elements under investigation with respect to the set limit values (see 12.2).

Step 10: Identify the acceptance criteria (see 12.3).

Step 11: Report the elements under investigation and indicate their concentration ranges.

Step 12: XRF screening is not suitable. Stop experiment.

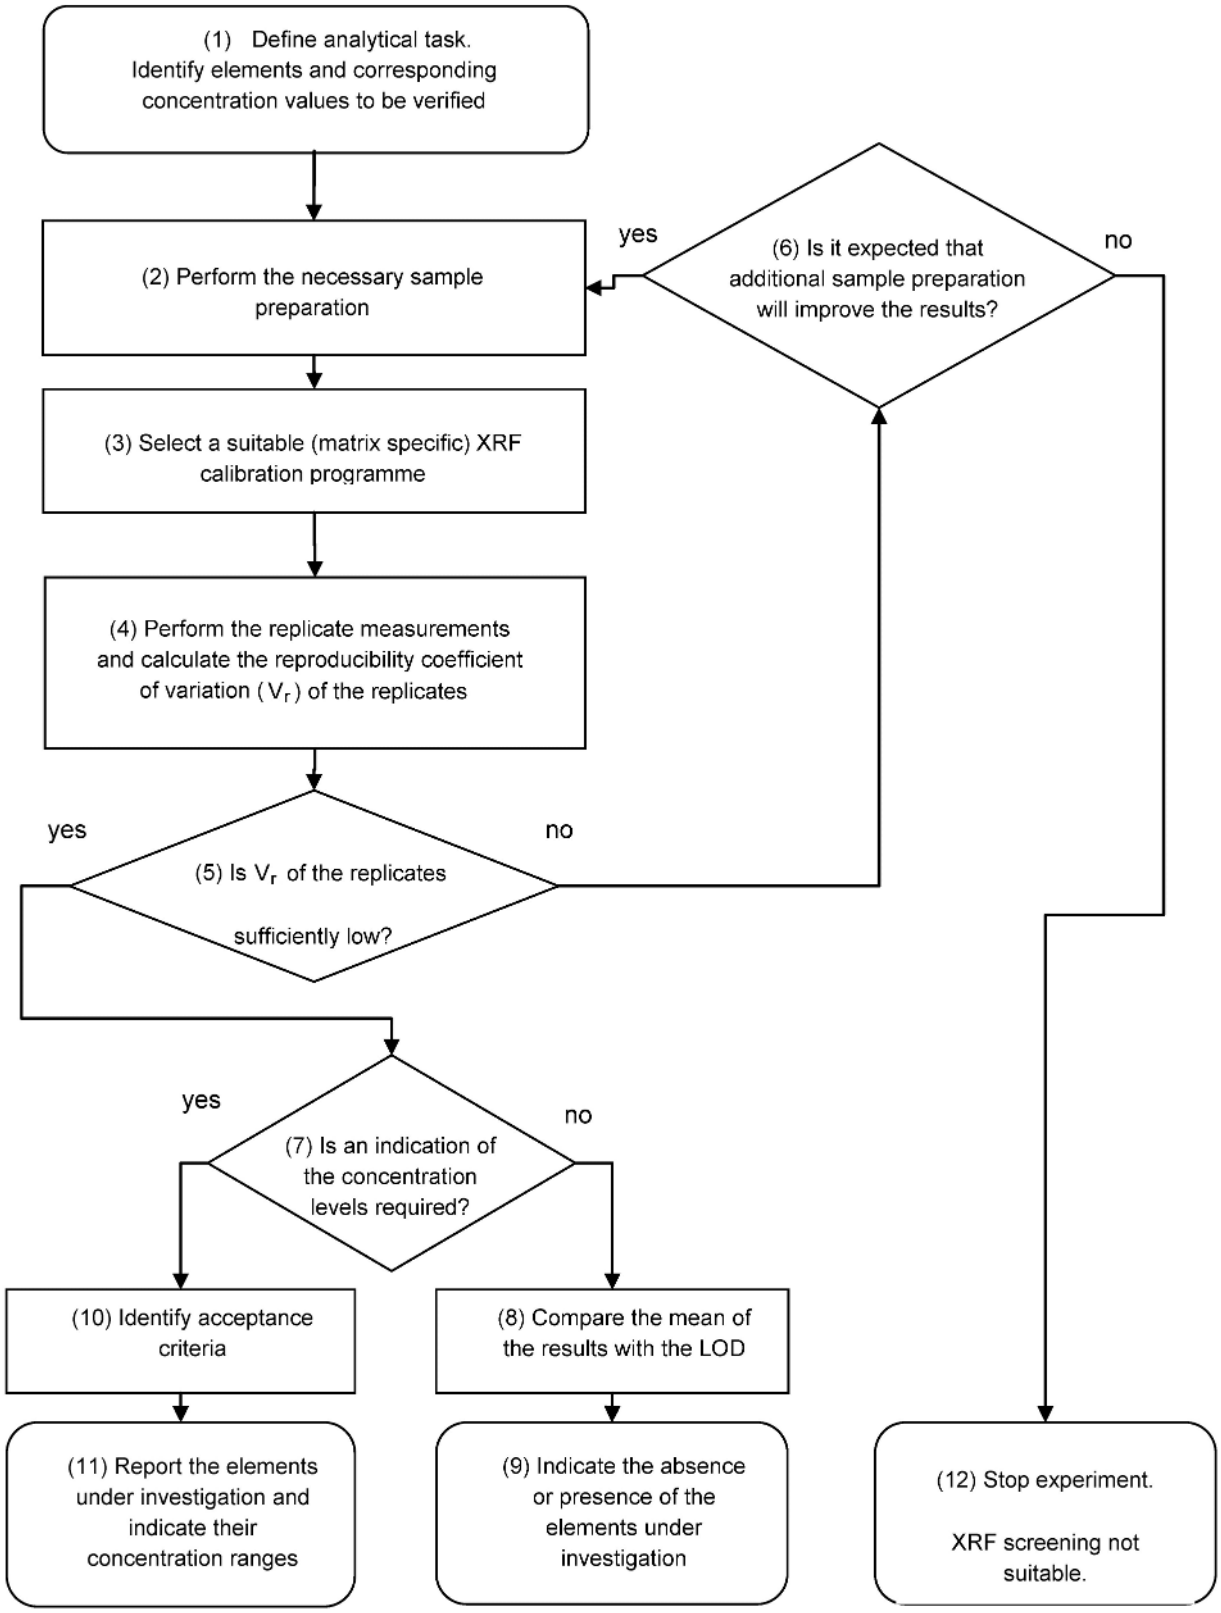

Figure 1 — Flowchart of the operational steps for screening experiments

9 Sample preparation

9.1 General

Milling and sieving are usually not applied because screening methods are used to obtain a preliminary result without or at least with limited sample preparation. Nevertheless in many cases the samples under investigation are very heterogeneous. Because XRF is a surface analysis technique, any sample preparation can improve the reliability of the results. The principles of EN 15002 shall be considered.

Be aware that the sample conditions, for example moisture content, organic content, particle size, high contents of some elements, have a significant influence on the quality of the results.

9.2 Sample preparation for direct measurement

In case of direct measurement (see 6.2) it is recommended to flatten and to compress the sample spot before measurement.

9.3 Sample preparation for filling cups

Sample cups provided with a suitable thin film foil are properly filled with sample material (as representative as possible) so that the bottom is completely covered. The material is shaken so that fine and coarse material are similarly distributed in the bottom of the cup. Use a spoon or a stamp to press the material tightly. Prepare at least three similar test samples from each sample spot.

9.4 Sample preparation for heterogeneous samples

Heterogeneous samples need further sample pretreatment if qualitative results with an indication of the concentration level are required. Drying of the collected sample and/or grinding of these sample using mortar and pestle might improve the quality of the results.

Heterogeneity is identified by high standard deviation values of the replicates (see Clause 8).

The moisture content of the sample has also an influence on the calculation of the concentration. The estimated value may be based on the wet sample.

10 Analysis

10.1 General

Follow the instrument manufacturer's instructions for set-up, conditioning, preparation and maintenance of the XRF spectrometer. Each XRF instrument should be operated according to the manufacturer's recommendations.

Before analysis, quality control samples shall be measured to check the instrument stability and the quality of the calibration in accordance to the manufacturer's instructions.

Select the proper calibration programme.

10.2 Direct *in situ* measurement (hand-held method)

Direct the X-ray probe to the sample, measure the sample and record the data (see 6.2). Repeat the procedure at least 3 times, preferably 5, on different spots. Evaluate the recorded data, calculate the relative repeatability standard deviation (V_r) and perform the assessment of the XRF screening experiment according to Clause 12.

Licensed copy: Lee Shau Kee Library, HKUST, Version correct as of 03/01/2015, (c) The British Standards Institution 2013

NOTE Measurement time commonly used varies between 30 s and 90 s for each measurement.

10.3 Measurement by using a mounted hand-held XRF instrument or a small portable closed XRF instrument

Instead of measuring *in situ*, samples can be collected and placed into a sample cup.

Either a hand-held instrument mounted on a stand (see 6.3) or a small portable bench top instrument (see 6.4) can be used.

In case of a bench top system introduce the filled sample cup into the sample holder. In case of a mounted hand-held instrument place the sample cup in front of the X-ray window at a fixed position according to the technical notes of the instrument supplier.

Measure the sample and record the data. Repeat the procedure at least 3, preferably 5, times by collecting samples from different spots. Evaluate the recorded data, calculate the relative repeatability standard deviation (V_r) and perform the assessment of the XRF screening experiment according to Clause 12.

NOTE Measurement time commonly used varies between 30 s and 90 s for each measurement.

11 Calculation of the result

The concentrations of the analytes are calculated by the software programme from the measured intensity using the calibrations curves previously set up. The results are expressed as elements in terms of mg/kg or mass percentages.

12 Assessment of the XRF screening measurement

12.1 General

The XRF screening is performed in order to determine the elemental composition of waste materials for on-site verification, i.e. to ensure that the waste accepted at a landfill is the same as described in the accompanying documents, and that it is in accordance with the basic characterization and/or compliance testing.

One of the following two issues is to be considered:

— identification of the presence or absence of the elements under investigation with respect to the set limit values;

— indication of the concentration range of the elements under investigation.

12.2 Identification of the presence or absence of the elements under investigation

The objective of the XRF screening methods is to identify the presence or absence of elements under investigation with respect to the set limit values. Therefore it is essential to avoid false negatives.

A limit value may be legally defined but it can be also any concentration value which is of interest in a specific investigation.

For this purpose, the experimental limit of detection (LOD) shall be known, or shall be determined from experimental results of at least three replicates. Calculate from the data of the replicate measurements the mean and the standard deviation for all relevant elements.

Licensed copy: Lee Shau Kee Library, HKUST, Version correct as of 03/01/2015, (c) The British Standards Institution 2013

The LOD is calculated as:

$$LOD = 3 \times s \quad (2)$$

where

LOD is the limit of detection

s is the standard deviation

If the calculated mean of the measured concentration is higher than the LOD, then this value indicates the presence of the element under consideration. Otherwise it should be stated that the indicative concentration value is less than the LOD.

12.3 Indication of the concentration range of the elements under investigation

If an indication of the concentration value is requested, the XRF screening method is able to give an overview of the elemental composition of the sample by expressing it in terms of concentration ranges.

Therefore it is necessary to define acceptance levels indicating the empirical tolerance of deviation of the determined mean result.

By comparing the measured XRF values of the elements under investigation with the indicated values (as defined in the basic characterization and/or described in the accompanying documents) and taking into consideration the defined acceptance criteria, it can be verified whether the waste composition is similar to what has been described in the documents.

In Annex C the relations between the elemental concentration determined and identification or acceptance criteria are explained.

13 Quality control

13.1 Drift correction procedure

XRF instruments, once calibrated, tend to be stable over long periods of time. Small amounts of instrumental drift can be corrected by analysing stable monitor samples as frequent as performance experience indicates.

For EDXRF spectrometers, an energy calibration shall be performed on a regular basis, as defined by the manufacturer’s instructions.

13.2 Blank test

Carry out a blank test to verify that no contamination exists in the spectrometer or on the probe window.

NOTE As blank sample a matrix adapted material, e.g. silicon dioxide, a polytetrafluoroethylene (PTFE) block or clean sand can be used.

13.3 Reference materials

Verify the trueness of the results by applying the procedure to one or more reference materials not used for calibration and covering the concentration range of interest (see also 7.4).

The element content of the reference material used shall be in accordance with the trigger values.

14 Test report

The test report shall include at least the following information:

a) a reference to this European Standard;

b) description and identification of the sample;

c) which processes (including sample preparation), procedures and apparatus were used;

d) documentation which XRF configuration was used (see 6.1 to 6.4);

e) a proof on the significance of true negatives and documentation of element specific LODs;

f) results of the determination expressed as mg/kg or mass percentages;

g) date(s) of performance(s) of test(s);

h) any details not specified in this European Standard or which are optional, and any other factors which may have affected the results.

Corrections or additions to a test report after issue shall be made only by a further document suitably marked, e.g. “Amendment/Addendum to test report serial number (or as otherwise identified)”, and shall meet the relevant requirements of the preceding paragraphs.

(informative)

Examples of instrumentation

In this annex examples are given of hand-held instruments and a compact bench top instrument, together with the different modes of operation.

In Figure A.1 a direct measurement on the sample using a pistol-like hand-held XRF instrument is shown.

In Figure A.2 a direct measurement using a hand-held XRF instrument in direct contact with the sample, but with the aid of a stand, is presented.

In Figure A.3 and Figure A.4 hand-held XRF instruments mounted on a stand and using sample cups filled with the sample are shown. In Figure A.4 the XRF instrument is supplementary equipped with a protective radiation shield which shall be closed when measuring.

In Figure A.5 a compact portable bench top XRF instrument is presented.

Annex C
(informative)

Evaluation of the acceptance criteria

C.1 Uncertainty

Any XRF measurement is characterized by an uncertainty in the resulting value of the concentration of an element in the sample. Uncertainty (U) is the parameter expressing the dispersion of the values that could reasonably be attributed to the measurand. Uncertainty of measurement comprises in general many components. Some of these components may be evaluated from the statistical distribution of the results of series of measurements and can be characterized by a standard deviation (s) of a series of repeated measurements. Other components may be evaluated from on the basis of experience or additional information.

C.2 Test of the absence of an element

It shall be identified whether or not an element is present in the sample. The basic criterion for 'absence' is that the calculated mean of the repeated measurements (M_{av}) is below the limit of detection (LOD), usually defined as 3 times the standard deviation (s):

$$M_{av} < 3 \times s \qquad \text{(C.1)}$$

C.3 Test of the documented concentration of an element

To decide whether or not an element is present in the waste sample with a concentration not higher than indicated in the document accompanying the waste (I_{doc}) the uncertainty (U) shall be estimated and used in the comparison of the average value of a series of repeated measurements (M_{av}). A condition is that both I_{doc} and M_{av} are higher than the limit of quantification (LOQ), commonly defined as 10 × s.

The basic acceptance criteria to decide whether an element is present in a sufficiently low concentration (lower than I_{doc}), is:

$$M_{av} + U \leq I_{doc} \qquad \text{(C.2)}$$

In this case, the waste involved can be accepted at the landfill.

In the case that $M_{av} - U < I_{doc} < M_{av} + U$ it cannot be decided whether the element concentration involved, is sufficiently low. If other evidence is present to accept the waste (e.g. more reliable results of repeated measurement after a sample preparation) a more accurate analytical method is necessary to enable a reliable decision.

In the case that $M_{av} - U > I_{doc}$ the indication is given that the element concentration of the element involved is too high to be accepted on the landfill. The waste should be refused at the landfill until an element determination with a well prepared sample in a laboratory will falsify the on-site result.

C.4 Estimation of uncertainty

To estimate the uncertainty (U) for XRF measurements in the field, the only parameter present is usually the standard deviation of the repeated measurements (s_r).

Based on s_r a number of methods to derive a value for U are possible. Some methods are presented.

a) Under regular laboratory condition and/or in case of a well-prepared (homogenized, small particles, flat) sample, it is generally accepted that a fair estimation of U is:

$$U = 2 \times s_r$$

In this particular case, and assuming a normal distribution of the measured values, the chance that the true value is in the range $M_{av} \pm U$ is 96 %. This percentage increases to 99 % for $U = 3 \times s_r$. As under field conditions during on-site verification, the well-preparedness of the sample is often not possible, and additional factors such as heterogeneity of the sample will enlarge the value of the uncertainty.

In those cases $U = k \times 2 \times s_r$ where the value of k can be a number based on expert view. Often a value of 2 or 3 is adopted.

b) Except for very low concentrations close to the LOD, the standard deviation in analytical measurements is dependent on the concentration of the measurand, as a result of the variability in the calibration function, according to $s = f\left(c^{1/2}\right)$.

To perform this dependence, either the variation in the calibration function should be known or repeated measurements at different element concentrations should be performed. Under conditions of on-site verification, these possibilities are usually not realizable.

To reckon with a higher s at higher element concentrations, a rough, practical ('quick and dirty') approach can be applied:

1) for M_{av} < 500 mg/kg, set the uncertainty range at $\frac{1}{5} \times M_{av}$ to $5 \times M_{av}$,

2) for 500 < M_{av} < 5 000 mg/kg, set the uncertainty range at: $\frac{1}{2} \times M_{av}$ to $2 \times M_{av}$,

3) for M_{av} > 5 000 mg/kg, set the uncertainty range at: $\frac{1}{1{,}3} \times M_{av}$ and $1{,}3 \times M_{av}$.

These numbers follow a Horwitz-like function [8].

When selecting identification criteria in case of applying XRF as a screening method at landfills, one should keep in mind to aim a control of documented values that should performed sufficiently quick while simultaneously protecting the environment.

Annex D
(informative)

Validation

A validation trial was performed to prove the capability of portable XRF systems for screening waste and contaminated soil. Five manufacturers were invited to participate in the validation trial. It was performed as a workshop where 6 different waste samples were analysed with in total 8 different portable XRF instruments. During the validation workshop the selected waste samples were identically prepared and presented in 6 different rooms (one room for each sample) in order to guarantee similar test conditions for all samples and for all manufactures. The participants of the trial were asked one by one to analyse all samples in fivefold (probing different spots). One manufacturer with a hand-held system measured directly on the sample while the others used the hand-held instrument in a bench top stand. In the latter case, a test portion was taken five times from the sample to be analysed and filled into a sample cup provided with a thin foil.

For details of the study see Reference [7]. The conclusions of this study are reported in CEN/TR 16176:2011 [5].

The following samples representative for landfills and waste incineration plants were selected. Sample material have been provided by waste handling plants from Germany and Belgium.

— sample 1: Pb granulate (particle size: 0 mm - 8 mm);

— sample 2: recycled construction waste (particle size: 0 mm - 10 mm);

— sample 3: waste wood (particle size: 0 mm - 2 mm);

— sample 7: shredder material (particle size: 0 mm - 2 mm);

— sample 8: contaminated soil;

— sample 11: slag from a municipal incineration waste (particle size: 0 mm - 8 mm).

As the samples S3 and S7 already had a particle size of less than 2 mm, no additional sample preparation was performed on these samples. From the other samples 2 subsamples were taken from the homogenized batches. One subsample was considered as the field study sample (conditions closely related to real field conditions). These samples were further indicated as ‘coarse’ samples. The second subsample was dried and finely ground with a planetary ball mill (indicative particle size < 250 µm) and are also further indicated as ‘fine’ samples.

Reference values (m_{REF}) for all elements were determined using the following methods:

— $HF:HNO_3$:HCl digestion (in triplicate) according to EN 13656 [1] and subsequent analysis of the digestion solution with ICP-AES, and

— EDXRF or WDXRF analysis according to EN 15309 [2]. The waste wood sample S3 was analysed with WDXRF using a semiquantitative measurement programme. These results can only be considered as indicative. The other samples were analysed with the EDXRF system with polarized light using a precalibrated geological calibration programme.

If elemental results were available from ICP-AES analyses, these values were used as reference values, otherwise the XRF results were defined as reference values.

The results are presented in Tables D.1, D.2, D.3, D.4, D.5, D.6, D.7, D.8, D.9 and D.10. More details related to the evaluation according to predefined acceptance levels are reported in CEN/TR 16176:2011 [5].

British Standards Institution (BSI)

BSI is the national body responsible for preparing British Standards and other standards-related publications, information and services.

BSI is incorporated by Royal Charter. British Standards and other standardization products are published by BSI Standards Limited.

About us

We bring together business, industry, government, consumers, innovators and others to shape their combined experience and expertise into standards -based solutions.

The knowledge embodied in our standards has been carefully assembled in a dependable format and refined through our open consultation process. Organizations of all sizes and across all sectors choose standards to help them achieve their goals.

Information on standards

We can provide you with the knowledge that your organization needs to succeed. Find out more about British Standards by visiting our website at bsigroup.com/standards or contacting our Customer Services team or Knowledge Centre.

Buying standards

You can buy and download PDF versions of BSI publications, including British and adopted European and international standards, through our website at bsigroup.com/shop, where hard copies can also be purchased.

If you need international and foreign standards from other Standards Development Organizations, hard copies can be ordered from our Customer Services team.

Subscriptions

Our range of subscription services are designed to make using standards easier for you. For further information on our subscription products go to bsigroup.com/subscriptions.

With **British Standards Online (BSOL)** you'll have instant access to over 55,000 British and adopted European and international standards from your desktop. It's available 24/7 and is refreshed daily so you'll always be up to date.

You can keep in touch with standards developments and receive substantial discounts on the purchase price of standards, both in single copy and subscription format, by becoming a **BSI Subscribing Member**.

PLUS is an updating service exclusive to BSI Subscribing Members. You will automatically receive the latest hard copy of your standards when they're revised or replaced.

To find out more about becoming a BSI Subscribing Member and the benefits of membership, please visit bsigroup.com/shop.

With a **Multi-User Network Licence (MUNL)** you are able to host standards publications on your intranet. Licences can cover as few or as many users as you wish. With updates supplied as soon as they're available, you can be sure your documentation is current. For further information, email bsmusales@bsigroup.com.

BSI Group Headquarters

389 Chiswick High Road London W4 4AL UK

Revisions

Our British Standards and other publications are updated by amendment or revision.

We continually improve the quality of our products and services to benefit your business. If you find an inaccuracy or ambiguity within a British Standard or other BSI publication please inform the Knowledge Centre.

Copyright

All the data, software and documentation set out in all British Standards and other BSI publications are the property of and copyrighted by BSI, or some person or entity that owns copyright in the information used (such as the international standardization bodies) and has formally licensed such information to BSI for commercial publication and use. Except as permitted under the Copyright, Designs and Patents Act 1988 no extract may be reproduced, stored in a retrieval system or transmitted in any form or by any means – electronic, photocopying, recording or otherwise – without prior written permission from BSI.
