BS EN 61970-552:2016

BSI Standards Publication

Energy management system application program interface (EMS-API)

Part 552: CIMXML Model exchange format

National foreword

This British Standard is the UK implementation of EN 61970-552:2016. It is identical to IEC 61970-552:2016. It supersedes BS EN 61970-552:2014 which is withdrawn.

The UK participation in its preparation was entrusted to Technical Committee PEL/57, Power systems management and associated information exchange.

A list of organizations represented on this committee can be obtained on request to its secretary.

This publication does not purport to include all the necessary provisions of a contract. Users are responsible for its correct application.

Energy management system application program interface (EMS-API) - Part 552: CIMXML Model exchange format (IEC 61970-552:2016)

Interface de programmation d'application pour système de gestion d'énergie (EMS-API) -Partie 552: Format d'échange de modèle CIMXML (IEC 61970-552:2016) Schnittstelle für Anwendungsprogramme für Netzführungssysteme (EMS-API) -Teil 552: CIM-XML-Modell Austauschformat (IEC 61970-552:2016)

This European Standard was approved by CENELEC on 2016-11-01. CENELEC members are bound to comply with the CEN/CENELEC Internal Regulations which stipulate the conditions for giving this European Standard the status of a national standard without any alteration.

Up-to-date lists and bibliographical references concerning such national standards may be obtained on application to the CEN-CENELEC Management Centre or to any CENELEC member.

This European Standard exists in three official versions (English, French, German). A version in any other language made by translation under the responsibility of a CENELEC member into its own language and notified to the CEN-CENELEC Management Centre has the same status as the official versions.

CENELEC members are the national electrotechnical committees of Austria, Belgium, Bulgaria, Croatia, Cyprus, the Czech Republic, Denmark, Estonia, Finland, Former Yugoslav Republic of Macedonia, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, the Netherlands, Norway, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, Switzerland, Turkey and the United Kingdom.

INTERNATIONAL ELECTROTECHNICAL COMMISSION

ENERGY MANAGEMENT SYSTEM APPLICATION PROGRAM INTERFACE (EMS-API) –

Part 552: CIMXML Model exchange format

FOREWORD

- 1) The International Electrotechnical Commission (IEC) is a worldwide organization for standardization comprising all national electrotechnical committees (IEC National Committees). The object of IEC is to promote international co-operation on all questions concerning standardization in the electrical and electronic fields. To this end and in addition to other activities, IEC publishes International Standards, Technical Specifications, Technical Reports, Publicly Available Specifications (PAS) and Guides (hereafter referred to as "IEC Publication(s)"). Their preparation is entrusted to technical committees; any IEC National Committee interested in the subject dealt with may participate in this preparatory work. International, governmental and non-governmental organizations liaising with the IEC also participate in this preparation. IEC collaborates closely with the International Organization for Standardization (ISO) in accordance with conditions determined by agreement between the two organizations.
- 2) The formal decisions or agreements of IEC on technical matters express, as nearly as possible, an international consensus of opinion on the relevant subjects since each technical committee has representation from all interested IEC National Committees.
- 3) IEC Publications have the form of recommendations for international use and are accepted by IEC National Committees in that sense. While all reasonable efforts are made to ensure that the technical content of IEC Publications is accurate, IEC cannot be held responsible for the way in which they are used or for any misinterpretation by any end user.
- 4) In order to promote international uniformity, IEC National Committees undertake to apply IEC Publications transparently to the maximum extent possible in their national and regional publications. Any divergence between any IEC Publication and the corresponding national or regional publication shall be clearly indicated in the latter.
- 5) IEC itself does not provide any attestation of conformity. Independent certification bodies provide conformity assessment services and, in some areas, access to IEC marks of conformity. IEC is not responsible for any services carried out by independent certification bodies.
- 6) All users should ensure that they have the latest edition of this publication.
- 7) No liability shall attach to IEC or its directors, employees, servants or agents including individual experts and members of its technical committees and IEC National Committees for any personal injury, property damage or other damage of any nature whatsoever, whether direct or indirect, or for costs (including legal fees) and expenses arising out of the publication, use of, or reliance upon, this IEC Publication or any other IEC Publications.
- 8) Attention is drawn to the Normative references cited in this publication. Use of the referenced publications is indispensable for the correct application of this publication.
- 9) Attention is drawn to the possibility that some of the elements of this IEC Publication may be the subject of patent rights. IEC shall not be held responsible for identifying any or all such patent rights.

International Standard IEC 61970-552 has been prepared by IEC technical committee 57, Power systems management and associated information exchange.

This second edition cancels and replaces the first edition published in 2013. This edition constitutes a technical revision.

This edition includes the following significant technical changes with respect to the previous edition:

- a) New Clause 4 that defines the versioning of CIMXML format described in this document.
- b) Subclause 5.1, the statement on work flow support is removed.
- c) Subclause 5.2, Statement about mandatory header added. Rules how to use the header added. The discussion on management of multiple CIMXML documents and archives is removed.

IEC 61970-552:2016 © IEC 2016

- d) Subclause 5.3, FullModelDocumentElement removed, minor version added to profile URI and the meaning of the header is elaborated in Table 2.
- e) Subclause 6.2 the description of rdf:ID and rdf:about has been updated.
- f) Subclause 6.3 introduce the new urn:uuid form and discuss the backwards compatibility.
- g) New Subclause 6.4 added on support of older UUID formats.
- h) New Subclause 6.5 discussing object types added.
- i) Subclause 7.2.3.3, Position of header described and duplicate rows removed.
- j) Document identification and references between documents updated in Table 2 and Subclauses 7.2.3.4 and 7.2.4.6.
- k) Subclause 7.2.3.7, A compound element can never be a root element.
- 1) Subclause 7.2.3.9, description of compound containment added.
- m) Subclauses 7.2.3.4 and 7.2.4.7.3, More clarification of cascading delete.

The text of this standard is based on the following documents:

FDIS	Report on voting
57/1752/FDIS	57/1773/RVD

Full information on the voting for the approval of this standard can be found in the report on voting indicated in the above table.

This publication has been drafted in accordance with the ISO/IEC Directives, Part 2.

A list of all parts in the IEC 61970 series, published under the general title *Energy* management system application program interface (EMS-API), can be found on the IEC website.

The committee has decided that the contents of this publication will remain unchanged until the stability date indicated on the IEC website under "http://webstore.iec.ch" in the data related to the specific publication. At this date, the publication will be

- reconfirmed.
- withdrawn,
- replaced by a revised edition, or
- amended.

IMPORTANT – The 'colour inside' logo on the cover page of this publication indicates that it contains colours which are considered to be useful for the correct understanding of its contents. Users should therefore print this document using a colour printer.

INTRODUCTION

This part of IEC 61970 is part of the series of standards that define an Application Program Interface (API) for an Energy Management System (EMS).

IEC 61970-301 specifies a Common Information Model (CIM): a logical view of the physical aspects of an electric utility operations. The CIM is described using the Unified Modelling Language (UML), a language used to specify, visualize, and document systems in an object-oriented manner. UML is an analysis and design language; it is not a programming language. In order for software programs to use the CIM, it must be transformed into a schema form that supports a programmable interface.

IEC 61970-501 describes the translation of the CIM in UML form into a machine readable format as expressed in the Extensible Markup Language (XML) representation of that schema using the Resource Description Framework (RDF) Schema specification language.

This part of IEC 61970 specifies how the CIM RDF schema specified in IEC 61970-501 is used to exchange power system models using XML (referred to as CIMXML) defined in the 61970-45x series of profile standards, such as the CIM Transmission Network Model Exchange Profile described in IEC 61970-452.

ENERGY MANAGEMENT SYSTEM APPLICATION PROGRAM INTERFACE (EMS-API) –

Part 552: CIMXML Model exchange format

1 Scope

This part of IEC 61970 specifies the format and rules for exchanging modelling information based upon the CIM. It uses the CIM RDF Schema presented in IEC 61970-501 as the metamodel framework for constructing XML documents of power system modelling information. The style of these documents is called CIMXML format.

Model exchange by file transfer serves many useful purposes. Profile documents such as IEC 61970-452 and other profiles in the 61970-45x series of standards explain the requirements and use cases that set the context for this work. Though the format can be used for general CIM-based information exchange, specific profiles (or subsets) of the CIM are identified in order to address particular exchange requirements. The initial requirement driving the solidification of this specification is the exchange of transmission network modelling information for power system security coordination.

This part of IEC 61970 supports a mechanism for software from independent suppliers to produce and consume CIM described modelling information based on a common format. The proposed solution:

- is both machine readable and human readable, although primarily intended for programmatic access,
- can be accessed using any tool that supports the Document Object Model (DOM) and other standard XML application program interfaces,
- is self-describing,
- takes advantage of current World Wide Web Consortium (W3C) recommendations.

2 Normative references

The following documents are referred to in the text in such a way that some or all of their content constitutes requirements of this document. For dated references, only the edition cited applies. For undated references, the latest edition of the referenced document (including any amendments) applies.

IEC 60050, International Electrotechnical Vocabulary (all parts)

IEC 61970-501:2006, Energy management system application program interface (EMS-API) – Part 501: Common Information Model Resource Description Framework (CIM RDF) schema

W3C, RDF/XML Syntax Specification

W3C, XSL Transformations (XSLT)

W3C, Document Object Model (DOM)

3 Terms and definitions

For the purposes of this document, the terms and definitions contained in IEC 60050 (for general glossary) and IEC TS 61970-2 (for EMS-API glossary definitions), as well as the following apply.

3.1

Application Program Interface

API

set of public functions provided by an executable application component for use by other executable application components

3.2

Common Information Model

CIM

abstract model that represents all the major objects in an electric utility enterprise typically contained in an EMS information model

Note 1 to entry: By providing a standard way of representing power system resources as object classes and attributes, along with their relationships, the CIM facilitates the integration of EMS applications developed independently by different vendors, between entire EMS systems developed independently, or between an EMS system and other systems concerned with different aspects of power system operations, such as generation or distribution management.

3.3

CIMXML

serialisation format for exchange of XML data as defined in this document

3.4

Document Object Model

DOM

platform- and language-neutral interface defined by the World Wide Web Consortium (W3C) that allows programs and scripts to dynamically access and exchange the content, structure and style of documents

3.5

Document Type Definition

DTD

standard for describing the vocabulary and syntax associated with an XML document

Note 1 to entry: XML Schema and RDF are other forms that can be used.

3.6

Energy Management System

EMS

computer system comprising a software platform providing basic support services and a set of applications providing the functionality needed for the effective operation of electrical generation and transmission facilities so as to assure adequate security of energy supply at minimum cost

3.7

Hypertext Markup Language

HTML

mark-up language used to format and present information on the Web

3.8

Model

collection of data describing instances, objects or entities, real or computed. In the context of CIM the semantics of the data is defined by profiles, see: 4.9. Hence a model can contain equipment data, power flow initial values, power flow results etc.

Note 1 to entry: In power system analysis, a model is a set of static data describing the power system. Examples of Models include the Static Network Model, the Topology Solution, and the Network Solution produced by a power flow or state estimator application.

3.9

Profile

schema that defines the structure and semantics of a model that may be exchanged

Note 1 to entry: A Profile is a restricted subset of the more general CIM.

3.10

Profile Document

collection of profiles intended to be used together for a particular business purpose

Resource Description Framework

language recommended by the W3C for expressing metadata that machines can process simply

Note 1 to entry: RDF uses XML as its encoding syntax.

3.12

RDF Schema

schema specification language expressed using RDF to describe resources and their properties, including how resources are related to other resources, which is used to specify an application-specific schema

3.13

Real-World Object

objects that belong to the real world problem domain as distinguished from interface objects and controller objects within the implementation

Note 1 to entry: The real-world objects for the EMS domain are defined as classes in IEC 61970-301 Common Information Model.

Note 2 to entry: Classes and objects model what is in a power system that needs to be represented in a common way to EMS applications. A class is a description of an object found in the real world, such as a PowerTransformer, GeneratingUnit, or Load that needs to be represented as part of the overall power system model in an EMS. Other types of objects include things such as schedules and measurements that EMS applications also need to process, analyze, and store. Such objects need a common representation to achieve the purposes of the EMS-API standard for plug-compatibility and interoperability. A particular object in a power system with a unique identity is modeled as an instance of the class to which it belongs.

3.14

Standard Generalized Markup Language

international standard for the definition of device-independent, system-independent methods of representing texts in electronic form

Note 1 to entry: HTML and XML are derived from SGML.

Unified Modelling Language

object-oriented modelling language and methodology for specifying, visualizing, constructing, and documenting the artefacts of a system-intensive process

3.16

Uniform Resource Identifier

URI

Web standard syntax and semantic for identifying (referencing) resources (things, such as files, documents, images)

IEC 61970-552:2016 © IEC 2016

3.17

eXtensible Markup Language

XML

subset of Standard Generalized Markup Language (SGML), ISO 8879, for putting structured data in a text file

Note 1 to entry: This is an endorsed recommendation from the W3C. It is license-free, platform-independent and well-supported by many readily available software tools.

3.18

eXtensible Stylesheet Language

XSL

language for expressing style sheets for XML documents

4 CIMXML version

The CIMXML version is implemented as an XML processing instruction that appears before the CIMXML document, refer to Table 1.

Table 1 - CIMXML version

XML processing instruction	Version	Revision date
iec61970-552	2.0	2014-03-12

Example:

5 Model exchange

5.1 General

Model exchange typically involves the exchange of a collection of documents, each of which contains instance data, referred to as a model, and a header. The structure and semantics of each model as well as the header are described by a profile, which is not included in the exchanged data. The overall exchange is governed by a collection of profiles in a Profile Document.

A CIMXML document shall consists of a header and a model section.

A header section describes the content of the model section contained in a document e.g. the date the model was created, description etc. The header may also identify other models and their relationship to the present model. Such information is important when the models are part of a work flow where, for example, the models have relations to each other, e.g. a model succeeds and/or depends on another.

5.2 Rules for CIMXML documents and headers

A CIMXML document is described by a single header. Multiple headers in a CIMXML document are not allowed.

The header section shall always be the first element in a CIMXML document. The header section elements are

- FullModel element, refer to 7.2.3.4.
- DifferenceModel element, refer to 7.2.4.6.

The data in the model section is defined by one or more profiles listed within the header.

Elements in a CIMXML document may have references to elements (resources) in other CIMXML documents.

As a single header element is allowed in a CIMXML document the model section may only contain elements that the header can describe. If multiple headers are needed a CIMXML document shall be created for each header.

5.3 Model and header data description

A description of a model is attached as header data to the model. Figure 1 describes the model with header information.

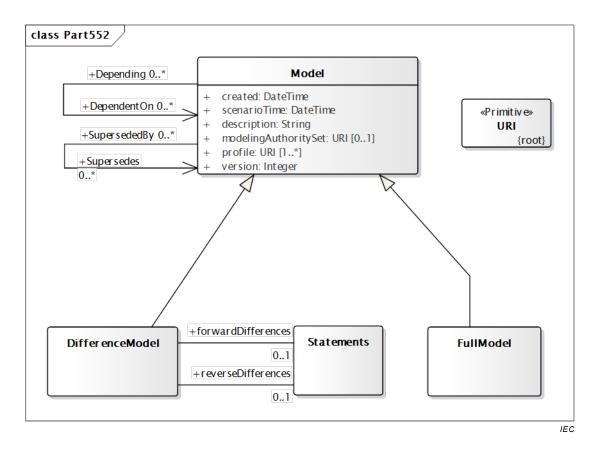

Figure 1 - Model with header

In Figure 1 the classes FullModel, DifferenceModel and Statements describe the model data while the header is described by the class Model. The following is a bottom up description of these classes:

- The Statements class represent a set of Definition (refer to 7.2.3.5) and/or Description (refer to 7.2.3.6) elements.
- The FullModel (refer to 7.2.3.4) class represent the full model header and its contents is described by the Model class.

- The DifferenceModel (refer to 7.2.4.6) class represents the difference model header. The content is described by the Model class, the association role forwardDifferences and association role reverseDifferences. Both association roles may have one set of Statements.
- The Model class describes the header content that is the same for the FullModel and the DifferenceModel. A Model is identified by an rdf:about attribute. The rdf:about attribute uniquely describe the model data and not the CIMXML document A new rdf:about identification is generated for created documents only when the model data has changed. A repeated creation of documents from unchanged model data should have the same rdf:about identification as previous document generated from the same model data.

The ordering of xml elements in the generated document is insignificant except for the FullModel element that always appear first in a document. The Model class attributes are described in Table 2.

Table 2 - Header attributes

Class	Attribute	Description
Model	created	The date when the document was created.
Model	scenarioTime	The date and time that the model represents, e.g. the current time for an operational model, a historical model or a future planned model.
Model	description	A description of the model, e.g. the name of person that created the model and for what purpose. The number of UTF-8 characters is limited to 2000.
Model	modelingAuthoritySet	A urn/uri referring to the organisation or role sourcing the model in the CIMXML document. Models from the same organisation or role but for different profiles shall have the same urn/uri.
Model	profile	A urn describing the Profiles that governs this model. It uniquely identifies the Profile and its version.
Model	version	A description of the version of the model sourcing the data in a CIMXML document. Examples are
		 Variations of the equipment model for the ModelingAuthoritySet Different study cases resulting in different solutions.
		The version attribute is an integer that is changed in synchronisation with the rdf:about identifier, refer to description of the Model class preceding this table.
Model	DependentOn	References to other models that the model in this document depends on, e.g. - A load flow solution depends on the topology model it was computed from
		A topology model computed by a topology processor depends on the network model it was computed from.
		The referenced models are identified by the FullModel rdf:about attribute (see 7.2.3.4) for full model documents and by DifferenceModel rdf:about attribute (see 7.2.4.6) for difference model documents.
		The references are maintained by the producer of the CIMXML document and the references are valid for the model with version and identifier (see description of Model class preceding this table) for which the document was created.
		The use of DependentOn by a consumer is optional. If a consumer of a document have also consumed the DependentOn documents it is expected that no dangling references are present in the currently consumed document.
Model	Depending	All documents depending on the model described by this document. This role is not intended to be included in any document exchanging instance data.

Class	Attribute	Description
Model	Supersedes	When a model is updated the resulting model supersedes the models that were used as basis for the update. Hence this is a reference to the models that are superseded by the model in this document. A model can supersede one or more models, for each superseded model one Supersedes reference is included in the header. The referenced models are identified by the FullModel rdf:about attribute (see 7.2.3.4) for full model documents and by DifferenceModel rdf:about attribute (see 7.2.4.6) for difference model documents.
		The references are maintained by the producer of the CIMXML document and are valid for the model with version and identifier (see description of Model class preceding this table) for which the document was created.
		The use of Supersedes by a consumer is optional. If a consumer of a document have also consumed the Supersedes documents it is expected that no dangling references are present in the currently consumed document.
Model	SupersededBy	All models superseding this model. This role is not intended to be included in any document exchanging instance data.

If a document is regenerated from a received and unchanged model all attributes in Table 2 shall be the same as in the originally received document. But if a received model is in any way modified none of the attributes may be different depending on the nature of the modifications.

DependentOn, Depending, Supersedes and SupersededBy describe the situation in the system where the document was generated at the time of generation. The use of the references in a receiving system is optional and a receiving system may or may not use the references depending on the use case, refer also to 5.4.

The profile attribute is a URI having the following format for IEC profiles:

• http://iec.ch/<committee>/<year>/<standard>-<part>/<profile>/<version>/<minor_version>

where text in <italic> is replaced by a describing text, e.g.

http://iec.ch/TC57/2011/61970-452/Equipment/2/1

The profile URI shall be treated as indivisible where the full string conveys the identification of a profile. Hence software is not supposed to parse and interpret substrings of the profile URI, e.g. year, standard, part etc.

Other organizations using the CIMXML serialization may have other profile URIs.

The UML in Figure 1 translates into CIMXML elements as follows:

- 1) A leaf class in Figure 1 (DifferenceModel, Statements and FullModel) appears as class elements under the document element (7.2.3.3).
- 2) Statement elements appear as Definition (7.2.3.5) or Description elements (7.2.3.6).
- 3) Literal attributes, e.g. Model.created, appears as literal property elements (7.2.3.8).
- 4) Roles appear, e.g. Model.Supersedes, as resource property elements (7.2.3.11).
- 5) Inherited attributes and roles appear directly as elements under the leaf class following the rules 3, 4 and 5 above.
- 6) A CIMXML model document is identified by a Model rdf:about attribute (implicit in the UML). Hence the roles DependentOn and Supersedes are references to the Model rdf:about attribute.
- 7) A document may be regenerated multiple times from the same model. Documents regenerated from an unchanged model keep the identification (Model rdf:about) unchanged from a previous document generated from the same model.

8) A DifferenceModel or FullModel document generated from the same model will have the same identification and same Supersedes. Hence a DifferenceModel and a FullModel document can be used interchangeably. However, if a receiving system want a full model equivalent with the model in the FullModel document the DifferenceModel document must be applied to a full model corresponding to the superseded.

5.4 Work flow

A work flow is described by a sequence of exchange events. The model description in 5.3 supports work flow events related in time with the Model.Supersedes attribute and events related to profiles with the Model.DependentOn attribute. An example of this is shown in Figure 2.

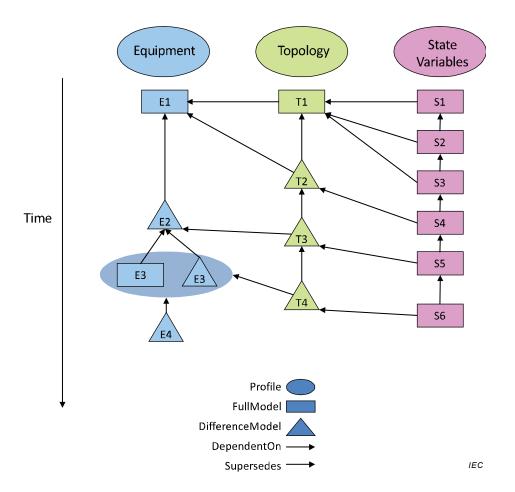

Figure 2 - Example work flow events

In this example, a solved network model is exchanged as a collection of models governed by a Profile Document comprising Equipment, Topology, and State Variables documents. The left time line in Figure 2 represents how the Equipment model document is exchanged over time. The center time line shows how new Topology results are exchanged over time and the Equipment models on which each depends. The right most time line shows how multiple State Variable documents are exchanged and the Topology documents on which they depend. Also note that the equipment model E3 is represented both by a full and a DifferenceModel document. The situation in Figure 2 represents a simple case. A more complex situation is shown in Figure 3.

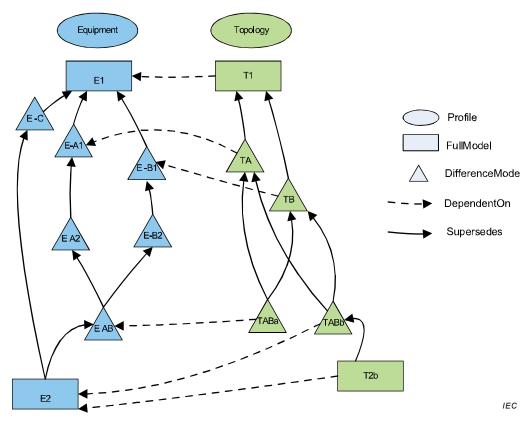

Figure 3 – Example work flow events with more dependencies

The CIMXML documents in Figure 3 may be created from a data modeller environment where multiple change tracks of a model appear in parallel, e.g. the equipment model has three tracks E-Ax, E-Bx and E-C that eventually merge into the full model E2 superseding the equipment model tracks.

A receiver of the CIMXML documents may use any of the topology documents TA, TB, TABa or T2b with the equipment model from E2. As the sender (the data modeller in this example) only verified T2b with E2 this is the only combination that is supposed to fit together. Concerning T2b the receiver may choose to apply TB and TABb to T1 instead of using T2b.

6 Object identification

6.1 URIs as identifiers

UUIDs (Universally Unique IDentifier), also known as GUIDs (Globally Unique IDentifier) can be used to identify resources in such a way that the

- identifiers can be independently and uniquely allocated by different authorities. This is a big advantage with the UUID;
- identifiers are stable over time and across documents.

If, in addition, the UUID is embedded in a Uniform Resource Name (URN) then the document can be simplified by the elimination of XML base namespace declarations (xml:base attributes). The URN is a concise, fixed-length, absolute URI.

The stability of identifiers over time also requires the following

- An identifier shall be created for any object when its existence become know. Note that objects in a model may or may not represent real physical equipment.
- An identifier for an object, e.g. a deleted object, is not allowed to be reused.

IEC 61970-552:2016 © IEC 2016

The standard for an URN containing a UUID is defined by the Internet Engineering Task Force RFC 4122,

RFC 4122 specifies the syntax of the URN and how the UUID portion following the last colon is allocated. The algorithm is aligned with, and technically compatible with, ISO/IEC 9834-8:2005 Information Technology, "Procedures for the operation of OSI Registration Authorities: Generation and registration of Universally Unique Identifiers (UUIDs) and their use as ASN.1 Object Identifier components" ITU-T Rec. X.667, 2004.

CIMXML elements are identified by a URI. Also other forms than the URI is allowed but not recommended.

A URI can have two forms:

- URL
- URN

The URL and URN forms have fundamentally different structures, i.e.:

- URL form; protocol://authority/path?query#fragment where the protocol in CIMXML is http
- URN form: urn:namespace:specification where the namespace in CIMXML is uuid.

The URN specification format is summarized below

- 8 character hex number
- a dash "-"
- 4 character hex number
- a dash "-"
- 4 character hex number
- a dash "-"
- 4 character hex number
- a dash "-"
- 12 character hex number

where characters are lower case conforming to W3C (ISO 8859/1 8-bit single-byte coded graphic character set known as Latin Alphabet No. 1.

An example of the URN form is shown below

"urn:uuid:26cc8d71-3b7e-4cf8-8c93-8d9d557a4846".

6.2 About rdf:ID and rdf:about

A CIMXML element can be identified by two different RDF constructs:

- rdf:ID
- rdf:about

In RDF the rdf:ID identification has the specific meaning that the identifier is unique within a document while the rdf:about identification means the identifier is unique within a name space. If the UUID name space urn:uuid is used for the rdf:about identification the identifiers are globally unique. Hence CIMXML promote using rdf:about identification in the UUID name space for all identifiers.

IEC 61970-552:2016 © IEC 2016

In the past an rdf:ID meant the introduction of a new resource or object while rdf:about meant a reference to an elsewhere introduced resource or object. This distinction is no longer used. As both are UUIDs they have the same meaning. For backwards compatibility both are allowed but the rdf:about form is the preferred.

Identifiers in the FullModel and DifferenceModel elements shall always use the rdf:about identification in the UUID name space, i.e. starting with "urn:uuid:".

6.3 CIMXML element identification

Resource identification is so central in RDF that all elements representing objects are identified with a rdf:ID or rdf:about XML attribute. All classes in CIM that inherit IdentifiedObject have the UML object identification attribute IdentifiedObject.mRID. The attribute is implicitly mapped to the rdf:ID/rdf:about XML attribute.

A CIMXML document may only use the URN form (see 6.1) as further described below.

CIMXML files contain XML elements describing CIM objects (ACLineSegments, Substations etc.). The CIM has lots of association roles that show up as references in the XML elements (typically as rdf:resource or rdf:about attributes). CIM data is exchanged in different CIMXML documents that depend on each other as described in Clause 4. Some references then cross CIMXML document boundaries. A consequence of this is that the identification of a CIM object must be stable during its life time. Otherwise referencing objects across document boundaries will break.

A common practice in object oriented systems is to assume all objects have an identifier that is unique in space and time which means:

- Different objects are assigned different identifiers.
- Identifiers once assigned are never reused even if the original object having it is gone.

The URN form as described in 6.1 is used as CIMXML element identification with the following differences

- The prefix "urn:uuid:" is replaced by an underscore "_". The underscore avoids a numeric starting character for the non-base part of the identifier. Starting the non-base part of the identifier with a numeric character is invalid RDF. The underscore is added in all cases to simplify parsers, even if the UUID starts with a non-numeric character.
- The prefix is defined as an xml:base="urn:uuid:"

Some examples:

- rdf:ID=" 26cc8d71-3b7e-4cf8-8c93-8d9d557a4846" the rdf:ID" form.
- rdf:about="# 26cc8d71-3b7e-4cf8-8c93-8d9d557a4846" the "hash" form.
- rdf:about="urn:uuid:26cc8d71-3b7e-4cf8-8c93-8d9d557a4846" the "urn:uuid:" form.

A receiver compatible with Edition 2 is supposed to be able to process all three forms.

A receiver compatible with Edition 1 is supposed to process the rdf:ID and rdf:about forms.

A producer compatible with Edition 2 should preferably only use the urn:uuid: form but is allowed to continue produce the rdf:ID and rdf:about forms.

A producer compatible with Edition 1 will produce the the rdf:ID and rdf:about forms.

6.4 Older ID formats

Over the past different resource identifiers (IDs) have been used, e.g. IDs not complying with 6.3. Hence systems in operation may be using object identifiers that do not comply with the formatting described in 6.3.

Identifiers not complying with 6.3 is not allowed to consist of more than 60 UTF-8 characters.

An ID change means that IDs according to the old format will no longer match with the new format without translation or mapping. As an ID is not self-describing such a translation is difficult to do.

Due to the far reaching consequences of an ID format change existing systems are allowed to continue use the old format for objects.

When such a system is upgraded to support Edition 2 of this document, new objects created in a system should use the ID format as described in 6.1. As a result objects created before the current edition of this document are allowed to keep the old ID format and no translation to the new format is required. This means that the system will support both the old and the new formats.

6.5 Object type

6.5.1 General

Elements in CIMXML are typed by the use of the Definition element (refer to 7.2.3.6). When multiple documents are exchanged it may be the case that the type for CIMXML elements with the same ID may have different types. This specification do not describe how a type change may be communicated.

6.5.2 References to a more generic type than the actual

In an exchange involving multiple profiles data about an object with the same ID may appear in multiple documents. A profile may describe data at a lower level in the inheritance hierarchy than actual type of the object. An example is the PowerSystemResource that has many relations with other classes. PowerSystemResource (PSR) itself is rarely instantiated but rather its subclasses. In a case where data describing a CIM class is split over many profiles it is allowed for each profile to use the level in the inheritance hierarchy that best fits the exchange. The reason for this is to make the profiling simple and only concern about the data of interest. An example of this is exchange locations, see Figure 4.

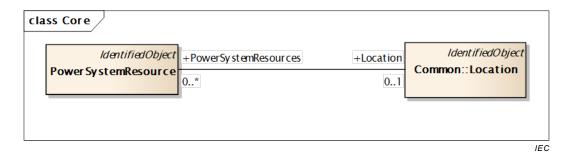

Figure 4 - CIM PSR - Location data model

The PSR class has a Location so a profile about exchange of locations will exchange the attribute PowerSystemResource.Location. But PSR is instantiated as a more specific class, e.g. Breaker, BusbarSystem etc. In a profile for exchange of location information it is impractical to enumerate all possible classes where an exchange of location is allowed also as the number of leaf classes will evolve over time. A stable profile for exchange of location is

just to use the PowerSystemResource class. The profile will then just include PowerSystemResource and a CIMXML element will look as follows:

```
<cim:PowerSystemResource rdf:about="_26cc8d71-12f1-4de9-9e68-125d95073a75" >
        <cim:PowerSystemResource.Location rdf:resource="#_26cc8d71-3b7e-4cf8-8c93-8d9d557a4847"/>
        <cim:PowerSystemResource >
```

CIM object data are typically described by several classes in the inheritance hierarchy starting with base classes like cim:IdentifiedObject and ending specific class like cim:Breaker.

Associations may exist at any level in this hierarchy. An example is the class cim:PowerSystemResource (PSR) that has many associations with other classes, e.g. cim:Location.

For an association in a profile one of the sides in the association is chosen, normally the lowest cardinality side. But it is important to select the most natural direction, i.e. it is more natural to state that "a PSR has a Location" than the opposite "a Location may have one or more PSRs". So depending on the level in the inheritance hierarchy where an association is located a resource property element (refer to 7.2.3.11) may refer to an abstract class in the inheritance hierarchy as is the case with the "a PSR has a Location" reference. As specific classes appear in a CIMXML document this can be interpreted so that a profile will have to enumerate all the specific classes inheriting the association, e.g. cim:Breaker, cim:Disconnector etc. This will clutter a profile and make it difficult to maintain.

A resource property element (refer to 7.2.3.11) may appear in two different cases

- A document where the object is defined by a definition element (refer to 7.2.3.6). In this case all properties are listed related to the definition of the CIM object so all classes will be enumerated anyway, i.e. there is no issue to with excessive enumeration.
- A document where an elsewhere defined object is referred to by a description element (refer to paragraph 7.2.3.6). In this case the specific object class does not matter and the object is referred to by an rdf:about attribute.

So elements that relate to elsewhere defined objects shall use the description element instead of the definition element in cases where properties from less specific classes are included. For the "a PSR has a Location" case this means the instead of including all subclasses of PSR just PSR Location is included in the profile and it will show up as a description element instead of a definition element in the CIMXML document. Refer to example in Figure 4.

A profile may describe the relation by referring from the PSR to Location resulting in a CIMXML breaker element having a location:

```
<cim:Breaker rdf:about="_26cc8d71-12f1-4de9-9e68-125d95073a75">
        <cim:PowerSystemResource.Location rdf:resource="#_26cc8d71-3b7e-4cf8-8c93-8d9d557a4847"/>
        </cim:Breaker >
```

To avoid including all types of equipment in a profile the reference can go the other way as in the below example:

To avoid using the same Location for many PSRs the cardinality Location.PowerSystemResource is lowered from 0..* to 1.

Using the solution proposed in this paragraph result in:

7 CIMXML format rules and conventions

7.1 General

Given the CIM RDF Schema described in IEC 61970-501, a power system model can be converted for export as an XML document (see Figure 5). This document is referred to as a CIMXML document. All of the tags (resource descriptions) used in the CIMXML document are supplied by the CIM RDF schema. The resulting CIMXML model exchange document can be parsed and the information imported into a foreign system.

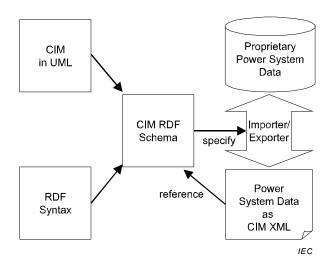

Figure 5 - CIMXML-based power system model exchange mechanism

7.2 Simplified RDF syntax

7.2.1 General

RDF syntax provides many ways to represent the same set of data. For example, an association between two resources can be written with a resource attribute or by nesting one element within another. This could make it difficult to use some XML tools, such as XSL processors, with the CIMXML document.

Therefore, only a subset of the RDF Syntax is to be applied in creating CIMXML documents. This syntax simplifies the work of implementers to construct model serialization and deserialization software, as well as to improve the effectiveness of general XML tools when used with CIMXML documents. The reduced syntax is a proper subset of the standard RDF syntax; thus, it can be read by available RDF de-serialization software.

Subclauses in 7.2 define a subset of the RDF Syntax. This simplified syntax is for exchanging power system models between utilities. The aim of the specification is to make it easier for implementers to construct de-serialization software for RDF data, to simplify their choices when serializing RDF data, and to improve the effectiveness of general XML tools such as XSLT processors when used with the serialized RDF data.

The reduced syntax is a proper subset of the standard RDF syntax. Thus, it can be read by RDF de-serialization software such as SirPAC [8]¹. In this, it differs from other proposals for a simplified syntax, such as [9], [10].

The reduced syntax does not sacrifice any of the power of the RDF data model. That is, any RDF data can be exchanged using this syntax. Moreover, features of RDF such as the ability to extend a model defined in one document with statements in second document are preserved.

7.2.2 Notation

The simplified syntax is defined in 7.2.3. Each kind of element is defined in a subclause beginning with a model of the element, followed by some defining text, and a reference to the RDF grammar. The semantics of the element are not detailed (refer to the RDF recommendation "W3C: RDF/XML Syntax Specification" for that information). The notation for the element model is as follows:

- 1) A symbol in *italics* in the position of an element type, attribute name or attribute value indicates the type of name or value required. The symbol will be defined in the text.
- 2) The symbol *rdf* stands for whatever namespace prefix is chosen by the implementation for the RDF namespace. Similarly the symbol *cim* stands for the chosen CIM namespace prefix.
- 3) A comment (<!-- comment text -->) within the element model indicates the allowed content.
 - A symbol in italics stands for a kind of element or other content defined in the text.
 - A construction (a | b) indicates that a and b are alternatives.
 - A construction a* indicates zero or more repetitions of a.
- 4) All other text in the model is literal.
- 5) The RDF grammar is described in 6.1, "W3C: RDF/XML Syntax Specification".

7.2.3 Syntax definition (normative)

7.2.3.1 **General**

The syntax definition is enriched with examples. The examples should help to get a better understanding of the formal syntax definition. The same example is used for several syntax definitions.

UTF-8 is the standard for file encoding. UTF-16 is not supported.

7.2.3.2 Name space URIs defined in this specification

The following name spaces are defined in this specification:

- cim-model-description uri described by xmlns:md
- difference-model-namespace-uri described by xmlns:dm

Their values are defined as:

- xmlns:md="http://iec.ch/TC57/61970-552/ModelDescription/1#"
- xmlns:dm="http://iec.ch/TC57/61970-552/DifferenceModel/1#"

¹ Numbers in square brackets refer to the bibliography.

7.2.3.3 Document element

```
<rdf:RDF xmlns:rdf=http://www.w3.org/1999/02/22-rdf-syntax-ns#
    xmlns:cim="cim-namespace-uri"
    xmlns:md="cim-model-description_uri"
    xml:base="urn:uuid:">
    <!-- Content: full-model (definition|description)* -->
</rdf:RDF>
```

Example:

```
<?xml version="1.0" encoding="UTF-8"?>
     xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
     xmlns:cim="http://iec.ch/TC57/2004/CIM-schema-cim10#"
     xmlns:md="http://iec.ch/TC57/61970-552/ModelDescription/1#"
     xml:base="urn:uuid:">
     <md:FullModel rdf:about="urn:uuid:26cc8d71-3b7e-4cf8-8c93-8d9d557a4846">
          <md:Model.created>2008-12-24T03:19:13</md:Model.created>
          <md:Model.Supersedes rdf:resource="urn:uuid:26cc8d71-3b7e-4cf8-8c93-
8d9d557a4847"/>
          <md:Model.DependentOn rdf:resource="urn:uuid:26cc8d71-3b7e-4cf8-8c93-
8d9d557a4848"/>
          <md:Model.version>32</md:Model.version>
     <md:Model.modelingAuthoritySet>http://polarenergy.com/2008/NorthPoleTSO</md:Mo
del.modelingAuthoritySet>
          <md:Model.description>Santa Claus made a study case peak load summer base
topology solution</md:Model.description>
          <md:Model.profile>http://iec.ch/TC57/61970-
452/Equipment/1</md:Model.profile>
     <md:Model.profile>http://iec.ch/TC57/61970-
452/EquipmentShortCircuit/1</md:Model.profile>
     </md:FullModel>
</rdf:RDF>
```

- 1) The element type is rdf:RDF.
- 2) The RDF namespace must be declared as http://www.w3.org/1999/02/22-rdf-syntax-ns#.
- 3) The CIM namespace must be declared. With newer versions of the CIM schema the version needs to be adjusted in the CIM name space. Parties exchanging documents have to agree on the used version.
- 4) Other namespaces may be declared.
- 5) The full model header element appears before the full model definition/description elements.

7.2.3.4 Full-model element

```
<md:FullModel rdf:about=model-uri>
     <!-- Content: (literal-property|resource-property|compound-
property)* -->
</md:FullModel >
```

```
<md:FullModel rdf:about="="urn:uuid:26cc8d71-...">
    <md:Model.created>2008-12-24T03:19:13</md:Model.created>
        <md:Model.Supersedes rdf:resource="urn:uuid:26cc8d71-a002-4c2b-bcf4-7bc97430bf87"/>
        <md:Model.DependentOn rdf:resource=urn:uuid:26cc8d71-a002-4c2b-bcf4-7bc97430bf88"/>
        <md:Model.version>32</md:Model.version>
        <md:Model.modelingAuthoritySet>http://polarenergy.com/2008/NorthPoleTSO</md:Model.modelingAuthoritySet>
        <md:Model.description>Santa Claus made a study case peak load summer base topology solution</md:Model.description>
        <md:Model.profile>http://iec.ch/TC57/61970-456/StateVariables/1</md:Model.profile>
</md:FullModel>
```

- 1) The full model element introduces a new model.
- 2) The value of the about attribute, model-uri, is a name chosen by the implementation. The model-uri uniquely identifies a document and is the name referenced by other documents, e.g. by Supersedes or DependentOn, as indicated in Figure 2.
- 3) The FullModel rdf:about attribute identifies a CIMXML document.

7.2.3.5 Definition element

```
<classname rdf:ID=identity>
    <!-- Content:
    (literal-property|resource-property|compound-property)*
    -->
</classname>
</classname rdf:about=resource-uri>
    <!-- Content:
    (literal-property|resource-property|compound-property)*
    -->
</classname>
```

Example:

1) The definition element introduces a new resource and gives its type. There are two forms: the first as an rdf:ID attribute and the second as an rdf:about attribute.

IEC 61970-552:2016 © IEC 2016

- 2) The element type, *classname*, is the XML qualified name of a class from the CIM schema or other schema declared as a namespace in the document element.
- 3) The value of the id attribute, *identity*, is chosen by the implementation. It must be unique in the document. (It is not necessarily related to the power system resource name.)
- 4) A Definition element with the same identification may appear in different documents. The meaning of this is that the properties in the different documents describe the same object and that the description is split over multiple documents. This is the case when data for a class is divided in multiple profiles and each profile is exchanged as its own CIMXML document.

7.2.3.6 Description element

```
<rdf:Description rdf:about=resource-uri>
    <!-- Content:
    (literal-property | resource-property | compound-property)*
    -->
</rdf:Description >
```

Example:

- The description element adds information about a resource introduced elsewhere in this or another document.
- 2) The resource-uri is a URN-reference that identifies the subject resource.
- 3) The Description element is used only in difference models (refer to 7.2.4). It is never used in full models.
- 4) A Description element with the same identification may appear in different documents. The meaning of this is that the properties in the different documents describe the same object and that the description is split over multiple documents. This is the case when data for a class is divided in multiple profiles and each profile is exchanged as its own CIMXML document.

7.2.3.7 Compound element

```
<classname>
  <!-- Content:
    (literal-property | resource-property | compound-property)*
    -->
  </classname>
```

Example:

1) The compound element introduces a structured value. The value does not represent a resource nor have any *identity*. It can only appear as the object of a property.

- 2) The element type, classname, is the XML qualified name of a compound class.
- 3) A compound element is treated as an indivisible unit. Hence a compound element is not supposed to be split in multiple elements having different sets of members. Refer also to 7.2.4.7.4.
- 4) A compound element is always part of another element and cannot be a root element.

7.2.3.8 Literal-Property element

```
<!-- Content: text -->
```

Example:

- 1) The literal-property element introduces a property and a literal value applying to the enclosing resource.
- 2) The element type, *propname*, is the XML qualified name of a property from the CIM schema or other schema declared as a namespace in the document element.
- 3) The content *text* is any XML text with <, >, and & escaped representing the value of the property.
- 4) Floating point numbers may slightly change due to rounding effects when imported and reexported again. This is allowed and need to be managed by applications, e.g. by use of a dead band in case the values are compared.
- 5) A Literal-Property element with the same propname may appear multiple times if the cardinality of the corresponding schema attribute is larger than 1.

7.2.3.9 Compound-Property element

```
<!-- Content: (compound-element) -->
```

Example:

1) The compound property element contains a compound element.

IEC 61970-552:2016 © IEC 2016

- 2) As a compound element may contain compound properties an indefinitely deep hierarchy is possible.
- 3) A Compound-Property element with the same propname may appear multiple times if the cardinality of the corresponding schema attribute is larger than 1.

7.2.3.10 Resource-Property element

cpropname rdf:resource=resource-uri/>

- 1) The resource-property element introduces a property and a resource as its value applying to the enclosing resource.
- 2) The element type, *propname*, is the XML qualified name of a property from the CIM schema or other schema declared as a namespace in the document element.
- 3) The resource-uri is an URN-reference that identifies a resource.
- 4) For relations with roles having cardinality greater than one the resource property element shall be repeated as many times as there are references
- 5) An association in a schema is bidirectional and has two roles (ends). Including Resource-Property elements for both roles is allowed but preferably elements for one side only is included. Then the side with the lowest cardinality is preferred but not required.
- 6) A Resource-Property element with the same propname may appear multiple times if the cardinality of the corresponding schema role is larger than 1.

Example 1 – URN-Reference:

The example contains two references one for a RegulationSchedule and the other to the parent represented as EquipmentContainer.

Example 2 – Enumeration:

The example defines the attribute value of SynchonousMachine.operatingMode as "generator". The operatingMode is specified in the CIM schema as the enumeration SynchronousMachineOperatingMode.

The example defines the attribute value of SynchonousMachine.operatingMode as "generator". The operatingMode is specified in the CIM schema as the enumeration SynchronousMachineOperatingMode.

Example 3 - Role with cardinality greater than one:

```
<cim:SynchronousMachine rdf:about="# 31dcf429-6bfb-4e2e-b299-642491b3abc1">
     <cim:IdentifiedObject.name>IN-2</cim:IdentifiedObject.name>
     <cim:SynchronousMachine.minimumMVAr>-9999</cim:SynchronousMachine.minimumMVAr>
     <cim:SynchronousMachine.operatingMode rdf:resource="http://iec.ch/TC57/2001/CIM-</pre>
schema-cim10#SynchronousMachineOperatingMode.generator"/>
     <cim:RegulatingCondEq.RegulationSchedule rdf:resource="#_cd32746f-a002-4c2b-</pre>
bcf4-7bc97430bf87"/>
     <cim:Equipment.EquipmentContainer rdf:resource="# 6cb8701a-12f1-4de9-9e68-</pre>
125d95073a75"/>
     <cim:Equipment.ReactiveCapabilityCurves rdf:resource="# 6cb8701a-12f1-4de9-9e68-</pre>
125d95073a76"/>
     <cim:Equipment.ReactiveCapabilityCurves rdf:resource="# 6cb8701a-12f1-4de9-9e68-</pre>
125d95073a77"/>
     <cim:Equipment.ReactiveCapabilityCurves rdf:resource="# 6cb8701a-12f1-4de9-9e68-</pre>
125d95073a78"/>
</cim:SynchronousMachine>
```

7.2.4 Syntax extension for difference model

7.2.4.1 **General**

The general syntax definition in the first part of this clause is used for partial and full model data exchange. Once the initial complete set of model data is exchanged, only updates are required to maintain the model as changes occur. In general, those changes can be specified as a set of differences between two models. The difference document is itself an RDF model (a collection of RDF statements) and therefore can be processed by an RDF infrastructure.

7.2.4.2 Example use case

To illustrate the DifferenceModel document approach to handling difference model updates, an example use case is provided. In this example, the participants are Regional Energy Co. and Network Power Co.:

- Each participant has a copy of a power system model, B1.
- Regional Energy Co. updates B1, to reflect forthcoming power system modifications, producing B2.
- Regional Energy Co. sends the differences between B1 and B2 to Network Power Co. as a difference model.
- Network Power Co. reviews and validates the difference model.
- Network Power Co. merges the difference model with its copy of model B1, to produce B2.

An alternative would have been for Regional Energy Co. to simply send Network Power Co. a copy of B2. However, B2 is a very large model and it is not feasible to validate it in any reasonable period of time. Validation is not entirely automated, but involves analysis by experts. Indeed, the best validation strategy for B2 may be to compare it to the previously validated B1. This brings us back to the need for a difference model.

A more complicated use case would involve more than two participants. Several peers of Regional Energy Co. would contribute difference models to Network Power Co. This use case would introduce issues of parallel model changes and concurrency conflict.

7.2.4.3 Requirements

Given two RDF models, B1 and B2, called base models, the requirement is for a difference model that:

- Represents the differences between the two base models.
- Is itself an RDF model (a collection of RDF statements) and therefore can be processed by RDF infrastructure.

- Efficiently represents a small difference between two large base models.
- When an object is deleted, the system applying the differences will not perform any the "cascading deletions", i.e. finding and deleting all other contained objects. Instead it is the responsibility of the system sourcing a deletion to include any cascading deletions.
- Remove operations are not reversible (at least, not from the information in the difference model).
- May contain information about itself such as authorship, purpose and date.
- May contain information to protect against conflicts arising when two difference models are created concurrently from the same base model.

The requirement to treat each difference document as a database commit operation is outside the scope of this service (i.e., a roll back functionality, if desired, is the responsibility of the receiving application, not the sending application). This is in recognition of the fact that the sending application may not be aware of changes made in the B2 model documents by other agents since the last update to B1.

7.2.4.4 Structure of difference document

Given two base RDF models, B1 and B2, the difference model is made up of four groups of statements, each encoded as a sequence of resource description structures:

- Forward difference statements, comprising statements found in B2, but not in B1.
- Reverse difference statements, comprising statements found in B1, but not in B2.
- Precondition statements, comprising statements found in both B1 and B2 and considered to be dependencies of the difference model in an application defined sense.

Any or all of the three groups can be empty.

The difference model itself is represented by a compound element of type dm:DifferenceModel.

The following properties apply to the difference model resource:

- dm:forwardDifferences is a property of the difference model whose value is a collection of statements (i.e., resources of type rdf:Statement) representing the forward difference statements.
- dm:reverseDifferences is a property of the difference model whose value is the collection of reverse difference statements.
- dm:preconditions is a property of the difference model whose value is the collection of precondition statements.

Header properties also apply to the difference model resource. These may indicate authorship, date and purpose. These properties can be drawn from the Dublin Core vocabulary or any other convenient schema.

The namespace for the difference model vocabulary, represented by the prefix dm: in the foregoing, is: http://iec.ch/TC57/61970-552/DifferenceModel/1#.

7.2.4.5 Preconditions and concurrency

The precondition statements are a subset of both B1 and B2 and carry no difference information. In simple, sequential model revision scenarios they can be omitted.

For a large shared model, sequential revision is not always feasible. Revisions are likely to be constructed concurrently by different participants, without reference to each other. Concurrency issues must be handled, but the conventional database-oriented approach of using locks to detect incompatible concurrent transactions is not feasible on a web-scale.

The precondition statements are an alternative to locks. Informally, they represent the information that would have been read-locked in an equivalent database transaction. Software agents that process difference models can check that the preconditions hold and, if not, warn of incompatible model revisions.

The choice of statements to include as preconditions is application-specific (as is the choice of which information to lock in a database transaction). Preconditions should include statements that would affect decisions of the agent that produced the model revision.

7.2.4.6 Difference model template

The following is a template for the conventional syntax of a difference model.

```
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"</pre>
    xmlns:cim="cim-namespace-uri"
    xmlns:md="cim-model-description uri"
    xmlns:dm="difference-model-namespace-uri"
    xml:base="urn:uuid:">
    <dm:DifferenceModel rdf:about=model-uri>
         <!--Content: (literal-property|resource-property|compound-property) *</pre>
         -->
         <dm:preconditions parseType="Statements">
              <!-- Content: (definition|description) * -->
         </dm:preconditions>
         <dm:forwardDifferences parseType="Statements">
              <!-- Content: (definition|description) * -->
         </dm:forwardDifferences>
         <dm:reverseDifferences parseType="Statements">
              <!-- Content: (definition|description) * -->
         </dm:reverseDifferences>
    </dm:DifferenceModel>
</rdf:RDF>
```

- 1) Simply for clarification with the namespace "dm" new statements are introduced that are valid extensions to the standard RDF syntax through the new property rdf:parseType, which is called Statements.
- 2) The content model of an element with rdf:parseType="Statements" is the same as the content model of the rdf:RDF element.
- 3) The content generates the same RDF statements as if it appeared in an rdf:RDF element.
- 4) The DifferenceModel rdf:about attribute identifies a CIMXML document.

7.2.4.7 Difference model usage

7.2.4.7.1 General

The following cases explain the usage of the difference model.

7.2.4.7.2 Add resource

The difference model contains for a given resource only a forward Difference statement if the particular is resource is added.

EXAMPLE:

The following example adds two new ACLineSegments each with its adjacent Terminals. The Terminals are linked to new ConnectivityNodes. Those ConnectivityNodes are assigned to a new VoltageLevel in an existing Substation.

```
<rdf:RDF
     xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
     xmlns:cim="cim-namespace-uri"
     xmlns:md="cim-model-description_uri"
     xmlns:dm="difference-model-namespace-uri"
     xml:base="urn:uuid:">
     <dm:DifferenceModel rdf:about="# 26cc8d71-3b7e-4cf8-8c93-8d9d557a4846">

4de9-9e68-125d95073a75"/>
                </cim:ConnectivityNode>
                <cim:VoltageLevel rdf:about="# 26cc8d71-12f1-4de9-9e68-</pre>
125d95073a75">
                      <cim:IdentifiedObject.name>230K</cim:IdentifiedObject.name>
                      <cim:VoltageLevel.Substation rdf:resource="# 26cc8d71-12f1-</pre>
4de9-9e68-125d95073a75"/>
                      <cim:VoltageLevel.BaseVoltage rdf:resource="# 26cc8d71-12f1-</pre>
4de9-9e68-125d95073a75"/>
                </cim:VoltageLevel>
           </dm:forwardDifferences>
     </dm:DifferenceModel>
</rdf:RDF>
```

7.2.4.7.3 Delete resource

The difference model contains for a given resource only a reverseDifference statement if the particular resource is deleted.

Cascading deletes are deletes where an object and its child objects (if any) are deleted. In a cascading delete it would be possible to just include the root or parent object in a CIMXML document. The receiver then has to figure out what child objects to delete. To make clear what objects are included in a cascading delete the creator of the CIMXML document shall include all objects as elements in the cascade. Including only the root or parent object is not allowed.

The EquipmentContainer-Equipment relation is a parent-child relation where deletion of an EquipmentContainer shall also result in a deletion of its child Equipment. Other examples of such parent child relations are

- EquipmentContainers also has a parent child relation, e.g. Station-VoltageLevel.
- PowerTransformer and it's TransformerEnds
- ConductingEquipment and its Terminals

The CIM does not currently specify the containment relations. As this information is missing it is up to an implementer to decide which relation is regarded a containment relation. This spoils interoperability. This is the reason to include all objects in a cascaded delete to indicate the sending systems interpretation of containment.

Delete elements shall have all its property elements included. Reason is that this enables reversing the delete operation and re-creates the object.

EXAMPLE:

The example below contains the deletion of a PowerTransformer with all resources that are hierarchically subordinated.

7.2.4.7.4 Update resource

The difference model contains for a given resource forwardDifference and reverseDifference statements if the resource is changed.

EXAMPLE:

The example below defines the move of the EnergyConsumer from 115k to 230k through the changed link from its Terminal to a different ConnectivityNode.

```
<rdf:RDF xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"</pre>
     xmlns:cim="cim-namespace-uri"
     xmlns:dm="difference-model-namespace-uri"
     xml:base="urn:uuid:">
     <dm:DifferenceModel rdf:about="#_26cc8d71-12f1-4de9-9e68-125d95073a75">
           <!-- Move EnergyConsumer load from 115K to 230K -->
           <dm:forwardDifferences rdf:parseType="Statements" >
                <rdf:Description rdf:about="# 39e4e305-1c70-4dcc-a423-45e4812dcd07">
                      <cim:Terminal.ConnectivityNode rdf:resource="# 612fa147-902c-</pre>
4f88-be3f-0302b3750b18"/>
                </rdf:Description>
           </dm:forwardDifferences>
           <dm:reverseDifferences rdf:parseType="Statements" >
                <rdf:Description rdf:about="# 39e4e305-1c70-4dcc-a423-45e4812dcd07">
                      <cim:Terminal.ConnectivityNode rdf:resource="#_5d74fc6a-b518-</pre>
4a3e-9e72-4827efd197cf"/>
                </rdf:Description>
           </dm:reverseDifferences>
     </dm:DifferenceModel>
</rdf:RDF>
```

For change of compound elements (7.2.3.7) the complete compound is replaced, i.e. the old element and all its members are removed by a reverse difference statement and added back with a forward difference statement.

7.3 CIMXML format style guide

A useful feature of RDF syntax is that it allows an arbitrary subset of a power system model to be serialized in a document. This is a two edged sword, however. A document produced by one party may not be usable by a second party if it does not contain all the properties expected. Moreover, a document containing a partial model may not be usable if the resource URN's do not agree with other documents.

The following guidelines apply to the content of a CIMXML document and help maximize the range of applications that can use it.

- 1) Include the likely primary key properties of each resource at the point it is introduced. For example, the cim:IdentifiedObject.name and cim:Equipment.EquipmentContainer properties are likely to be required properties.
 - Reason: a large class of applications will want to load a database with the model data. Many database schemas will require primary key values on insertion.
- 2) Include single-valued properties rather than their many-valued inverse. For example, use cim:Equipment.EquipmentContainer and not cim:EquipmentContainer.Equipments.
 - Reason: Because these properties are inverses, a statement predicated on one implies the converse statement predicated on the other. It is less error prone to include only one side and makes editing or transforming the document easier.
- 3) When encountering many to many relationships, there is usually a primary direction of reference. Include the primary reference rather than their many-valued inverse. For example, use cim:SynchronousMachine.MVArCapabilityCurves and not cim:MVArCapabilityCurve.SynchronousMachines, since the primary relationship is from SynchronousMachine to MVArCapabilityCurve.
 - Reason: Same reasons as for item 2 above.
- 4) When encountering a single-valued relationship with a single value inverse, include either one, but not both. Importing software needs to be designed to handle either direction of reference and infer the inverse.
 - Reason: Because these properties are inverses, a statement predicated on one implies the converse statement predicated on the other. This is less error prone, and arguably, makes editing or transforming the document easier.
- 5) Many valued properties, if used, appear as repeated property elements having the same property name.

7.4 Representing new, deleted and changed objects as CIMXML elements

The following cases exists for identification of elements and how they appear in full or difference models

- New objects are represented by the definition element (refer to 7.2.3.5) identified by a rdf:ID or rdf:about attribute in full or difference models.
- Deleted objects are represented by the definition element (refer to 7.2.3.5) identified by a rdf:ID or rdf:about attribute in difference models.
- Changed objects are represented by the description element (refer to 7.2.3.6) identified by a rdf:about attribute in difference models.
- An added property (e.g. internally a null value is changed to a valid value) is a change that appears only in the forward section of a difference model.
- A removed property (e.g. internally a valid value is changed to a null value) is a change that appears only in the backwards section of a difference model.

7.5 CIM RDF schema generation with CIM profile

This part of IEC 61970 discusses the generation of CIM RDF Schema. A CIMXML model exchange document uses a subset of the CIM to address the model exchange needs of a specific use case; see Part 400 series profile documents. A CIM profile defines that portion of the CIM that an importer and exporter of a CIMXML document should be expected to handle. The RDF Schema for a profile then contains only the classes and properties defined for that profile.

A RDF Schema file can be generated from the CIM UML model by an application having a user interface where the subset of the CIM UML model is interactively specified. The RDF Schema file can be used by an application to validate a CIMXML document, refer to Figure 6.

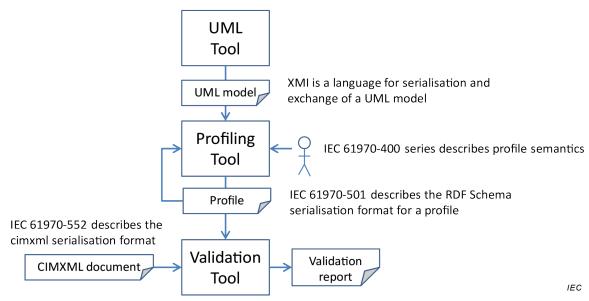

Figure 6 - Relations between UML, profile and CIMXML tools

Figure 6 describe the "UML model" at the top is used in a "Profiling tool" to generate a "Profile". A "Validation tool" can use an existing "Profile" to validate a "CIMXML document" and generate a "Validation report".

7.6 CIM extensions

The CIM RDF schema can be extended with new classes and attributes by providing a separate namespace. Because a separate namespace is used, the customized CIMXML documents clearly delineate what is CIM standard and what is custom. Several different custom extensions can exist and be clearly identified within the same XML document. When these customized documents are imported to information systems that know nothing about the extensions, the elements with the unknown tags can be simply ignored. The following declaration identifies an extended namespace "bpa".

```
xmlns:bpa="http://www.bpa.gov/schema/cim extension/2001may"
```

For example, we can add a non-CIM attribute, <code>OriginalPO</code>, to the <code>Breaker</code> class, as shown below. These customized tags for BPA can be simply ignored if a system import program is not interested in such extensions.

The RDF schema corresponding to this extension can be added to a separate RDF schema document thereby keeping the CIM RDF schema clearly separate and allowing each to evolve independently.

7.7 RDF simplified syntax design rationale

The following points explain some of the choices made in the simplified syntax.

- 1) The literal properties could be represented by property attributes (RDF "W3C: RDF/XML Syntax Specification" grammar clause 6.10). This would be more compact. However, property elements were chosen because they are easier to deal with in XSLT expressions. (For example, they can be sorted.) They also make it easier to represent multi-line text.
- 2) The syntax is flat, with a two-level resource/property structure. More deeply nested structures might be more compact. Moreover, a well-chosen nested structure might permit common queries to be more easily encoded in XSLT expressions. On the other hand, the flat structure was chosen because it is the simplest structure possible and is easy to produce and interpret. By avoiding any application dependency on the details of a nesting structure it should be a more portable syntax.
- 3) All resources are given a type at the time they are introduced (by the definition element). However, the RDF model allows a resource to be un-typed. In the present application, untyped resources are not required. However the difference model uses un-typed resources as described in 7.2.3.6.

British Standards Institution (BSI)

BSI is the national body responsible for preparing British Standards and other standards-related publications, information and services.

BSI is incorporated by Royal Charter. British Standards and other standardization products are published by BSI Standards Limited.

About us

We bring together business, industry, government, consumers, innovators and others to shape their combined experience and expertise into standards -based solutions.

The knowledge embodied in our standards has been carefully assembled in a dependable format and refined through our open consultation process. Organizations of all sizes and across all sectors choose standards to help them achieve their goals.

Information on standards

We can provide you with the knowledge that your organization needs to succeed. Find out more about British Standards by visiting our website at bsigroup.com/standards or contacting our Customer Services team or Knowledge Centre.

Buying standards

You can buy and download PDF versions of BSI publications, including British and adopted European and international standards, through our website at bsigroup.com/shop, where hard copies can also be purchased.

If you need international and foreign standards from other Standards Development Organizations, hard copies can be ordered from our Customer Services team.

Copyright in BSI publications

All the content in BSI publications, including British Standards, is the property of and copyrighted by BSI or some person or entity that owns copyright in the information used (such as the international standardization bodies) and has formally licensed such information to BSI for commercial publication and use.

Save for the provisions below, you may not transfer, share or disseminate any portion of the standard to any other person. You may not adapt, distribute, commercially exploit, or publicly display the standard or any portion thereof in any manner whatsoever without BSI's prior written consent.

Storing and using standards

Standards purchased in soft copy format:

- A British Standard purchased in soft copy format is licensed to a sole named user for personal or internal company use only.
- The standard may be stored on more than 1 device provided that it is accessible
 by the sole named user only and that only 1 copy is accessed at any one time.
- A single paper copy may be printed for personal or internal company use only.

Standards purchased in hard copy format:

- A British Standard purchased in hard copy format is for personal or internal company use only.
- It may not be further reproduced in any format to create an additional copy.
 This includes scanning of the document.

If you need more than 1 copy of the document, or if you wish to share the document on an internal network, you can save money by choosing a subscription product (see 'Subscriptions').

Reproducing extracts

For permission to reproduce content from BSI publications contact the BSI Copyright & Licensing team.

Subscriptions

Our range of subscription services are designed to make using standards easier for you. For further information on our subscription products go to bsigroup.com/subscriptions.

With **British Standards Online (BSOL)** you'll have instant access to over 55,000 British and adopted European and international standards from your desktop. It's available 24/7 and is refreshed daily so you'll always be up to date.

You can keep in touch with standards developments and receive substantial discounts on the purchase price of standards, both in single copy and subscription format, by becoming a **BSI Subscribing Member**.

PLUS is an updating service exclusive to BSI Subscribing Members. You will automatically receive the latest hard copy of your standards when they're revised or replaced.

To find out more about becoming a BSI Subscribing Member and the benefits of membership, please visit bsigroup.com/shop.

With a **Multi-User Network Licence (MUNL)** you are able to host standards publications on your intranet. Licences can cover as few or as many users as you wish. With updates supplied as soon as they're available, you can be sure your documentation is current. For further information, email subscriptions@bsigroup.com.

Revisions

Our British Standards and other publications are updated by amendment or revision.

We continually improve the quality of our products and services to benefit your business. If you find an inaccuracy or ambiguity within a British Standard or other BSI publication please inform the Knowledge Centre.
