Foreword

ISO (the International Organization for Standardization) is a worldwide federation of national standards bodies (ISO member bodies). The work of preparing International Standards is normally carried out through ISO technical committees. Each member body interested in a subject for which a technical committee has been established has the right to be represented on that committee. International organizations, governmental and non-governmental, in liaison with ISO, also take part in the work. ISO collaborates closely with the International Electrotechnical Commission (IEC) on all matters of electrotechnical standardization.

The procedures used to develop this document and those intended for its further maintenance are described in the ISO/IEC Directives, Part 1. In particular the different approval criteria needed for the different types of ISO documents should be noted. This document was drafted in accordance with the editorial rules of the ISO/IEC Directives, Part 2. www.iso.org/directives

Attention is drawn to the possibility that some of the elements of this document may be the subject of patent rights. ISO shall not be held responsible for identifying any or all such patent rights. Details of any patent rights identified during the development of the document will be in the Introduction and/or on the ISO list of patent declarations received. www.iso.org/patents

Any trade name used in this document is information given for the convenience of users and does not constitute an endorsement.

For an explanation on the meaning of ISO specific terms and expressions related to conformity assessment, as well as information about ISO's adherence to the World Trade Organization (WTO) principles in the Technical Barriers to Trade (TBT), see the following URL: http://www.iso.org/iso/foreword.html

The committee responsible for this document is Technical Committee ISO/TC 268, *Sustainable development in communities*, Subcommittee SC 1, *Smart community infrastructures*.

Introduction

In the foreseeable future, urban density is likely to increase, resulting in further urbanization complexity. From this perspective, a "smart community" approach is an important concept to address such urban challenges by integrating different forms of infrastructures in a rational and efficient manner.

An important aspect of a smart community is integrating infrastructures as "a system of systems". Until now it has not been possible to ensure consistency across infrastructure types to meet the requirements for smart community infrastructures as owners have focused on just assembling solutions to each subsystem of infrastructures.

In order to ensure consistency of smart community infrastructures as a whole, first, functions of each subsystem need to be clarified and arranged based on the needs for a smart community, and secondly, the perspectives of various stakeholders and lifecycle of infrastructures need to be considered.

Thus, a new framework is needed to develop a procedure followed by all stakeholders in order to establish an orchestration function of each smart community infrastructure component and to achieve information sharing as well as consensus amongst the stakeholders.

For this purpose, ISO/TC 268/SC 1/AHG 1 "Common framework for development and operation of smart community infrastructures" was established to conduct preliminary studies to develop international standards to formulate a framework which realizes well-functioning smart community infrastructures as a whole, considering their characteristics, i.e. "a system of systems", having various stakeholders, and long lifecycle. These standards will formulate technical procedures for stakeholders to achieve their accountability in developing, operating and maintaining smart community infrastructures as a system of systems. This document presents the results of the study conducted in the AHG. The framework aims to ensure consistency between smart community infrastructures without overlapping with existing work (see Figure 1). It incorporates the metrics as a KPI of the development, operation and maintenance methodology.

Figure 1 — Scope of the framework

Smart community infrastructures — Common framework for development and operation

1 Scope

This document outlines the basic concept of a common framework for the development and operation of smart community infrastructures. The framework describes the planning, development, operation and maintenance methodology to facilitate the harmonization of each infrastructure as a part of a smart community and ensures that the interactions between multiple infrastructures are well orchestrated.

The framework is applicable to all processes of smart community infrastructures' life cycle (from conceptual design through planning, development, operation, maintenance, redevelopment and feedback). The infrastructures to be covered are energy, water, transportation, waste management, ICT and others.

The framework can be adopted by all relevant stakeholders who are engaged in planning, development and operation of smart community infrastructures, including planners, developers, business operators and suppliers. The framework is intended to cover the processes in which these stakeholders are engaged, such as management, organizational structure, analyses and design methods, and documentations.

2 Possible issues and solutions in developing and operating smart community infrastructures

2.1 Possible issues and solutions

Features of smart community infrastructure can be described as below:

— Smart community infrastructure is infrastructure that has a high level of financial and resource efficiency and convenience for people.

— To achieve the above state, smart community infrastructure

— has orchestration function to achieve synergy effect of multiple types of infrastructures to improve financial and resource efficiency and convenience for people, and

— maintains its efficiency in adaptive manners against any changes of city's circumstances including disasters and demographic changes to improve financial and resource efficiency and convenience for people (resiliency / dependability).

NOTE 1   Efficiency means output performance divided by resource input.

NOTE 2   The orchestration function can be implemented by either a centralized approach or a decentralized autonomous approach.

Since smart community infrastructures have the features shown above, they may have three characteristics different from those of conventional infrastructures (see Figure 2). Issues are identified from the characteristics as below. In addition, solutions corresponding to these issues are extracted as elements of the framework.

— Issues due to "a system of systems" and long life cycle:

— Difficulties in ensuring consistency among components, without which functionality of the whole system of smart community infrastructures cannot occur.

— Considerable influence by interference of external systems or interactions among components onto the quality and performance of smart community infrastructures as a whole.

— Issue due to the participation of many different stakeholders:

— Various interest and wide range of responsibilities dispersed among stakeholders.

In Table 1, specific issues, extracted from the main three issues described above, are summarized along with solutions that will effectively accommodate these issues.

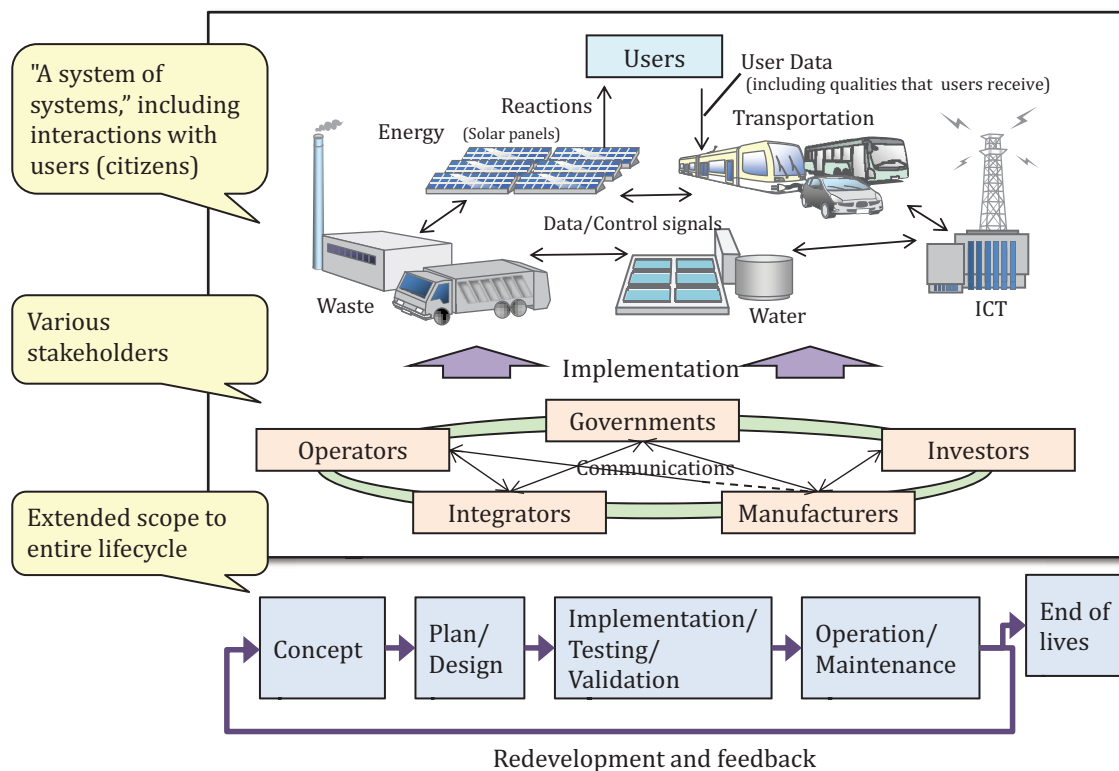

Figure 2 — Characteristics of smart community infrastructures

Table 1 - Possible issues and solutions in developing and operating smart community infrastructures[1] (1 of 2)

Main issues	Specific issues extracted from main issues	Case examples of each specific issue	Solutions (Elements of the framework)
Difficulties in ensuring consistency among components, without which functionality of the whole system of smart community infrastructures cannot occur.	Value added to smart community infrastructures as a whole cannot be shown simply by verifying the performance of each subsystem or component resulting in undervaluation of the appeal integrated infrastructure benefits.	Case example (a) [See 2.2.1.1]	Element (A): Allocation of specifications to each component and validation of the allocating procedures [See 3.2.1].
	Smart community infrastructures may not achieve their target value simply by assembling high performance subsystems / components unless the consistency among the subsystems / components is ensured.	Case example (b) [See 2.2.1.2]	
Considerable influence by interference of external systems or interactions among components onto the quality and performance of smart community infrastructures.	Fluctuation in the parameters of various interactions (in short terms as well as long terms) could curb performance of smart community infrastructures.	Case example (c)~(e) [See 2.2.2.1]	Element (B): Specifications associated with interaction including investigation between outside/inside smart community infrastructures and adopt countermeasures into planning and operation (See 3.2.2).
	Due to limitations in capabilities of external infrastructures, requirements and needs of smart community infrastructures as a whole cannot realised.	Case example (f) [See 2.2.2.2]	

[1] 2.2 and 3.2 of this Technical Report refer to Table 1.

Table 1 - Possible issues and solutions in developing and operating smart community infrastructures[1] (2 of 2)

Main issues	Specific issues extracted from main issues	Case examples of each specific issue	Solutions (Elements of the framework)
Various interest and wide range of responsibilities dispersed among stakeholders.	Stakeholders in different situations make communication complicated.	Case example (g) (See 2.2.3.1)	**Element (C):** Process to facilitate the information sharing and communication among stakeholders (See 3.2.3).
	Many stakeholders of different smart community infrastructures hardly bring efficient information sharing resulting in difficulties in planning and development of smart community infrastructures.	Case example (h) (See 2.2.3.2)	Need comprehensive discussion at the community level, in addition to the elements (A) to (C).

2.2   Case examples of issues

2.2.1   Difficulties in ensuring consistency among subsystems, without which functionality of the whole system of smart community infrastructures cannot occur

2.2.1.1   Value added to smart community infrastructures as a whole cannot be shown simply by verifying the performance of each subsystem resulting in undervaluation of the appeal integrated infrastructure benefits (see Figure 3)

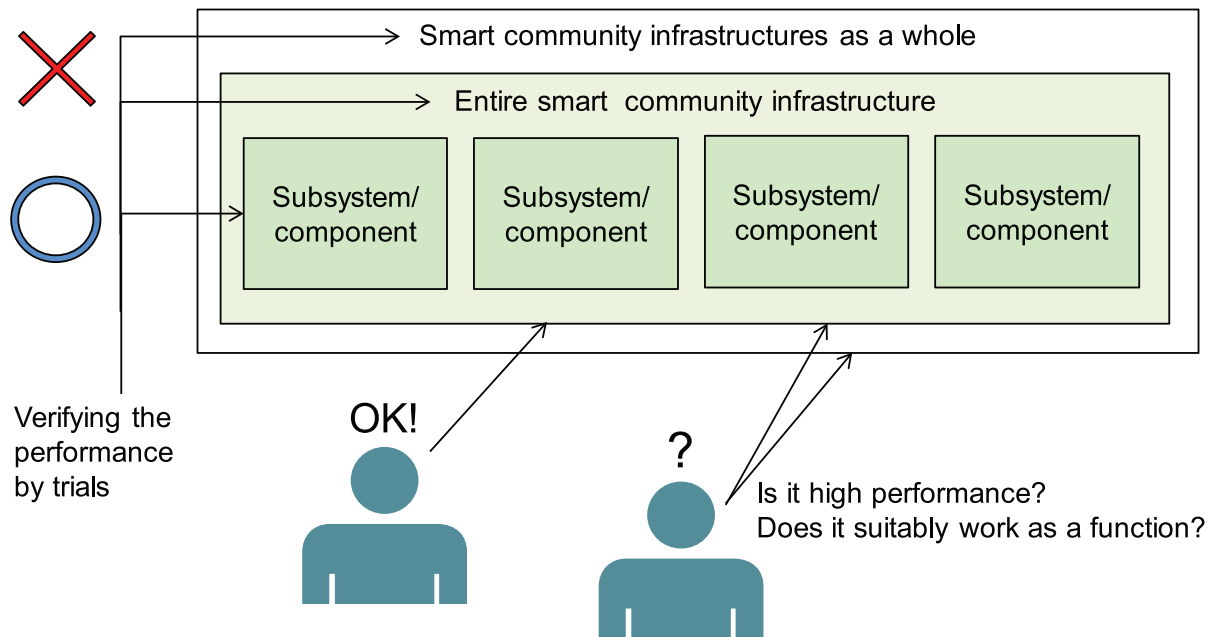

Figure 3 — Difficulty in showing added value to smart community infrastructures as a whole

Case example (a): If the value added of the community brought by the smart community infrastructures is not visible, it would not appeal to users sufficiently to get a return on the investment.

City developers generate profit by increasing value of smart communities (including intangible elements such as convenience, comfort, low costs and so on), by introducing smart community infrastructures. To give an example, if heat supply system is introduced to a community, which can reuse exhaust heat from sewage treatment facility, it will be an opportunity to appeal to the users who are willing to live in a community where energy bill and carbon emission are reduced despite comparatively high rent or water bill. However, in case the cooperation between sewage treatment facility and heat supply system is not defined and the expected amount of heat reuse is not clear, it is hard to appreciate much the reduction of energy bill and carbon emission would occur and thus would have limited appeal to end users. As a result, developers will not be able to raise rent or water bill and eventually fail to yield a fair return for additional investment in the heat reuse system.

2.2.1.2 Smart community infrastructures may not achieve their target value simply by assembling high performance components unless the consistency among the subsystems is ensured (see Figure 4)
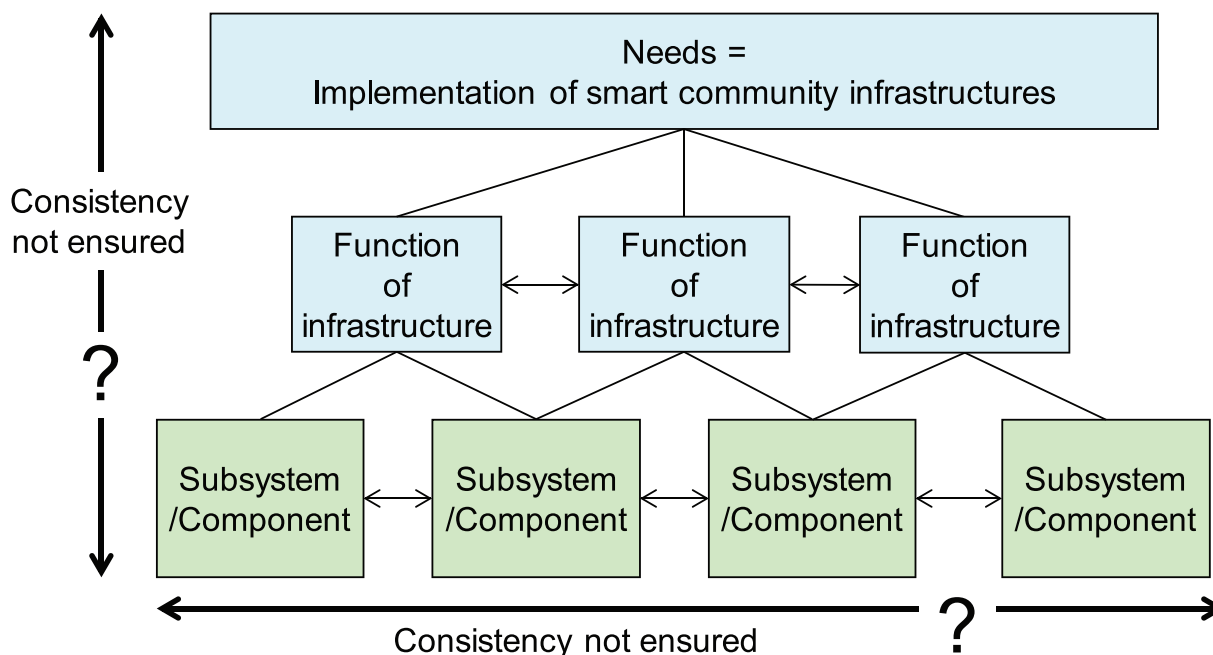

Figure 4 — Difficulty in achieving their target value unless the consistency among the subsystems is not ensured

Case example (b): Inconvenience on passengers due to unconnected and inconsistent services among transportation infrastructures

In a large scale project to integrate individual smart community infrastructures, business risks are often high. In such a situation, projects are divided into small parts or functions to be managed by a particular operator or supplier to make them develop their own infrastructures in their specific technical field. Thus, operators and suppliers focus their arrangements only on the component that they are directly responsible. Such a situation discourages communication on the consistency of broader smart community infrastructures.

For example, Japan Railways have operated a large service network of surface transportation in the country by operating ferries and buses besides railroads, which are of all different forms of infrastructures. Thus, the customers easily travel anywhere by using the network because all transportation services are organically connected, even between a bullet train or Shinkansen and bus servicers. On the other hand, private railroad, ferry and bus companies independently schedule and dispatch their respective trains, ferries or buses to carry their own customers in their small local territories. Thus, when such customers go on a trip across Japan, they are forced to make arrangements for their travel by themselves resulting in inconvenience and reducing satisfaction from travel, making changes between different modes unrealized.

2.2.2   Considerable influence by interference of external systems or interactions among components onto the quality and performance of smart community infrastructures

2.2.2.1   Fluctuation in the parameters of various interactions (in short-terms as well as long terms) could curb performance of smart community infrastructures (see Figure 5)
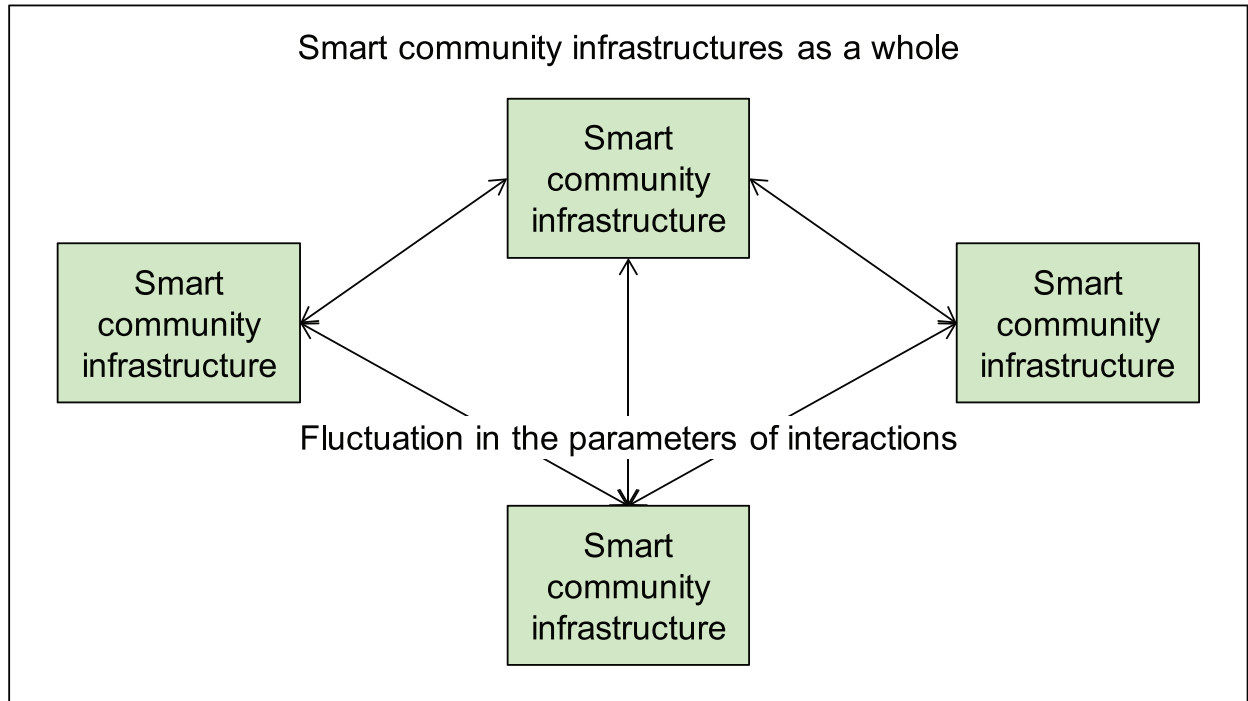

Figure 5 — Fluctuations in the parameters of various interactions

Case example (c): It is necessary to consider the changes in input and output generated from new interactions, different from those of conventional infrastructures, with other infrastructures.

Waste management system, for instance, used to be "the end point" to dispose of waste generated in a community. However, within a smart community it works also as "the starting point" to supply the recycled or upcycled resources back to the community.

As shown in Figure 6, it is necessary to control the changes in input (waste) and output (recycled resources) according to the demands to the resources. It is also needed to determine who should be responsible in case of supply shortages.
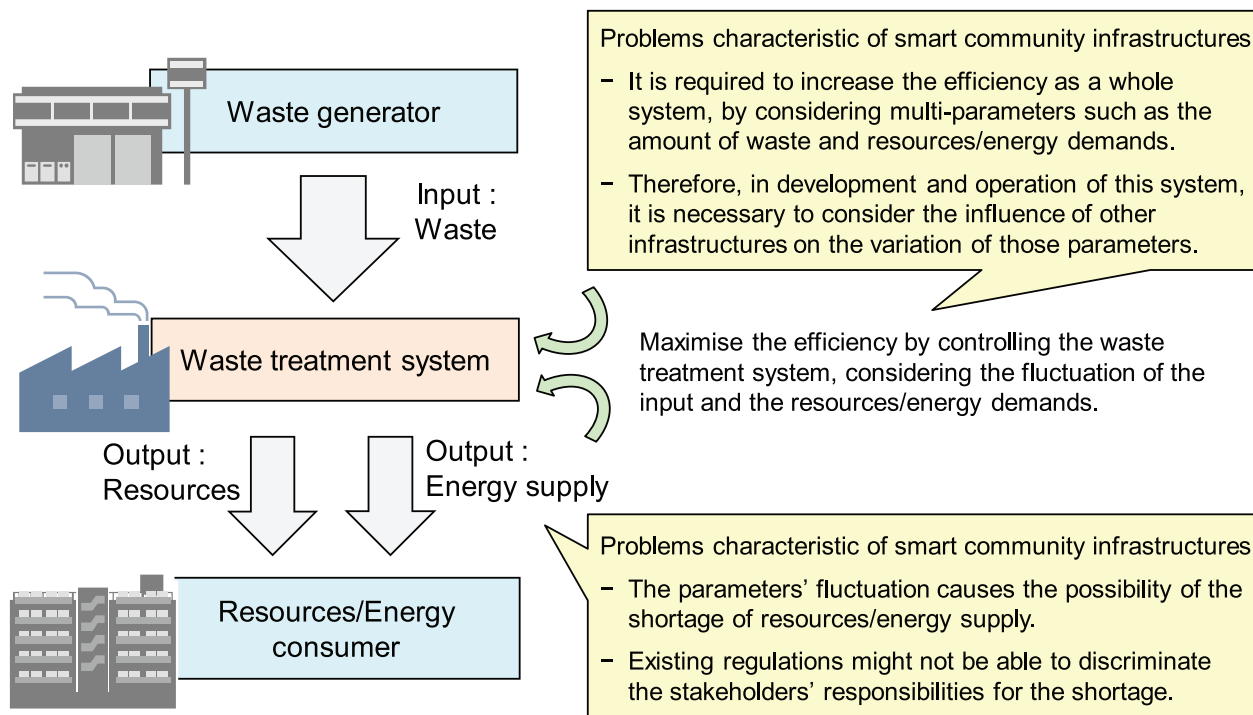

Figure 6 — Case (c): Waste management system

Case example (d): In the integration of smart community equipment with networks internal and external to smart communities, safety and reliability need to be ensured.

Take electric vehicle (EV) for example, it is necessary to consider when it is plugged into the grid, how it may affect other components connected with the grid (see Figure 7). For the safety of EV, it is necessary to take into account the grid and the component connected to it.

Problems characteristic of smart community infrastructures
- It won't be able to assure the safety and reliability of infrastructure without considering not only EVs' defects but also their influence on EPS or other infrastructure.
- For this purpose, it is necessary to ensure their safety and reliability by taking measures as a whole system including other infrastructure.
- In addition, it will be necessary to develop a framework that can clarify the responsibilities and make the stakeholders communicate together effectively.

Electric power facilities

Battery systems

Figure 7 — Case (d): EV plugged to the grid

Case example (e): Changes in neighbouring regions, such as urbanization, should be considered for development of smart community infrastructures.

Some smart community infrastructures, such as transportation or energy, are interconnected with the external systems of neighbouring regions. For this reason, changes in the status of neighbouring regions should be considered to realize full efficiency of infrastructures. When there is a change in population in neighbouring regions, the demand against smart community infrastructures may change accordingly.

2.2.2.2   Due to limitations in capabilities of external infrastructures, requirements and needs of smart community infrastructures as a whole cannot be realized (see Figure 8)
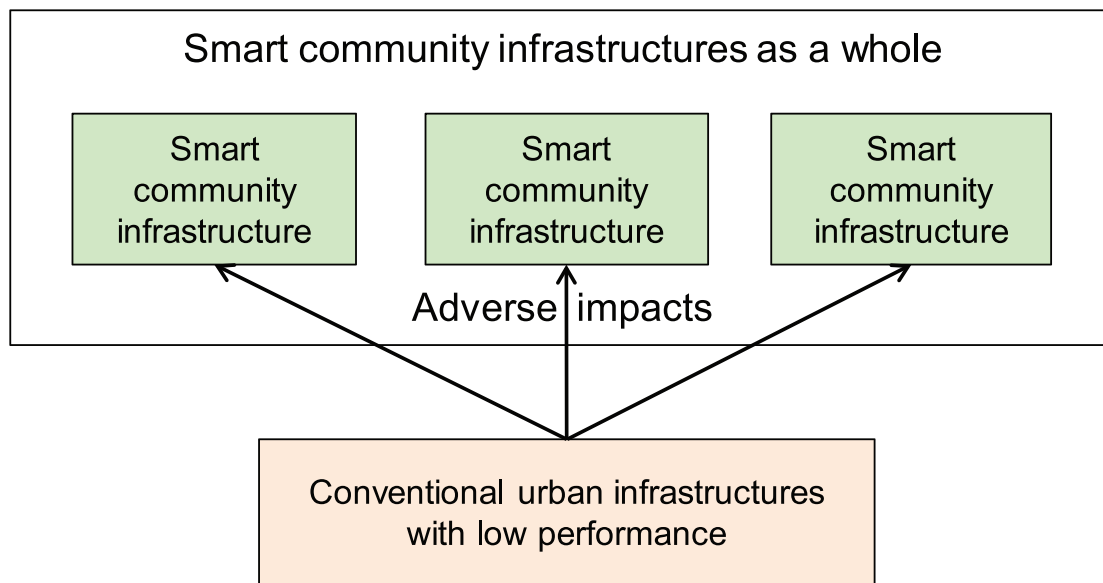

Figure 8 — Limitations in capabilities of external infrastructures

Case example (f): Difference in capacities and qualities of external infrastructures may cause inefficiency and malfunction to bring damages or losses.

Sewage farms built by foreign investment in a developing country would not work as expected without well prepared sewage line network. Reduced efficiency due to poor conditions of interacting infrastructures may cause damages or losses.

2.2.3   Various interest and wide range of responsibilities dispersed among stakeholders

#### 2.2.3.1   Stakeholders in different situations make communication complicated (see Figure 9)

Figure 9 — Stakeholders in different situations

Case example (g): Developers have different departments to manage different infrastructures, or different authorities govern different infrastructures, due to which communication among stakeholders becomes complicated.

In development and operation of smart community infrastructures as a whole, concise and frequent communication is desired among different stakeholders in various fields. In a number of municipalities as a developer, for instance, one department generally manages one specific infrastructure. Therefore, in order to discuss the whole picture of smart community infrastructures as integrated planning, full communication should be arranged inter-departmentally.

In Bangkok, Thailand, three companies run transportation services; State Railways of Thailand for heavy rail and an airport rail link, Mass Rapid Transit Authority of Thailand for metros and Bangkok Mass Transit System Public Company Limited for tramways on viaducts. There is a key junction Downtown Bangkok or Makkasan Station for the airport rail link and Phetchaburi Station for a metro. Both lines were planned around the same time, but the two important stations are not connected despite that they have a large number of passengers. Passengers who change trains at the stations are forced a walk for 10 min on an unsheltered bustling street. This is a typical example given by poor communication among different infrastructure stakeholders, brought by competition or friction among them.

2.2.3.2   Many stakeholders of different smart community infrastructures hardly bring efficient information sharing resulting in difficulties in planning and development of smart community infrastructures (see Figure 10)
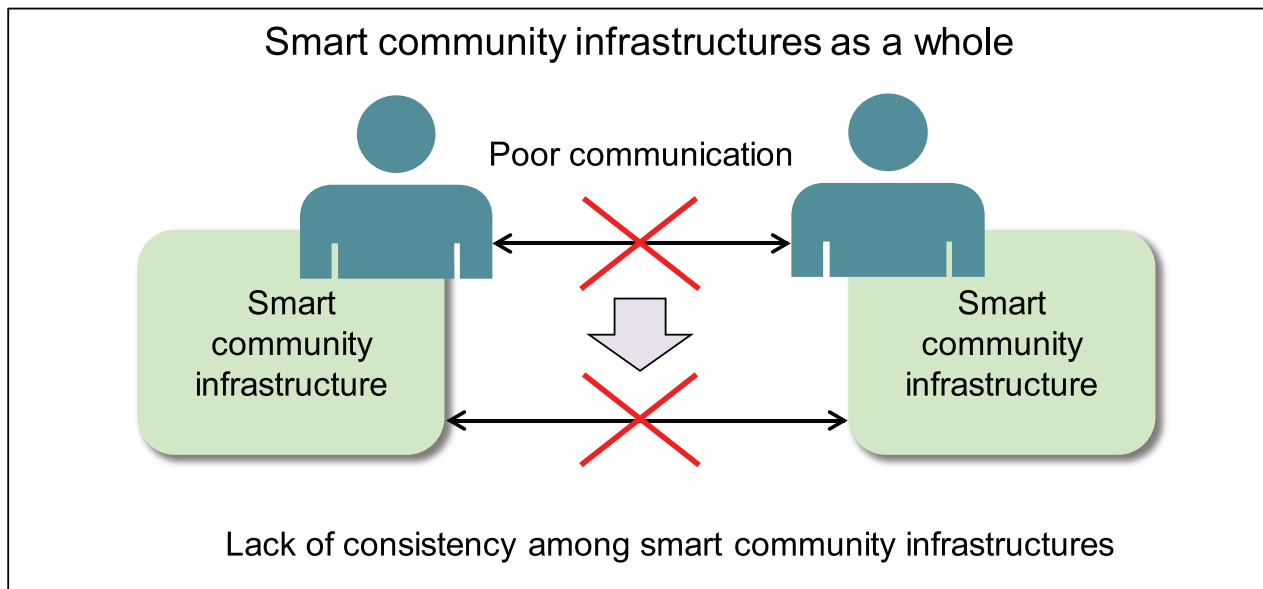

Figure 10 — Many stakeholders of different smart community infrastructures hardly bring efficient information sharing

Case example (h): Difficulty in sharing information related to individual infrastructures makes it complicated to analyse issues for discussing solutions to improve the efficiency of smart community infrastructures as a whole.

For instance, there are some solutions for highly efficient medical care system:

— development of transportation infrastructures for efficient travel by patients;

— development of ICT infrastructures for telemedicine system;

— combination of both solutions.

In order to select the optimal option and to determine the appropriate functions of transportation and ICT infrastructures, it is necessary to analyse the current context relating them.

For this, a process is needed for information sharing among stakeholders of individual infrastructures. Without such process, it would not be possible to obtain necessary information for analysis in timely manner, and thus to discuss how to improve the efficiency of smart community infrastructures as a whole (e.g. allocation of functions or roles to individual infrastructures).

2.3   Related topics to be clarified when developing and operating smart community infrastructure

It is important that the following points are clarified in the course of development and operation of infrastructures (not only smart community infrastructures but also conventional infrastructures). It is expected to discuss whether the framework should involve functions to clarify these points:

— the entities that own the system and their accountability;

— the entities that are responsible for the governance of the system; Entities that fund the governance;

— the entities that are responsible for the management of the system;

— the maintenance model of the system; The process by which the needs for maintenance is determined;

— the beginning and the end of the system. The process and means that are decided;

— ways one accesses/connects to the system and becomes part of it;

— the stakeholders in the system;

— methods to measure system degradation and system failure; and their indicators;

— ways to reconcile different ownership systems in different countries;

— a process to create the initial system; The entities to be invited;

— whether an entity can decline to join the system or not; The response to the refusing entity;

— ways to accommodate changes or to help the system evolve.

3 Outline and benefits of the framework

3.1 General

To resolve each issue arising in Clause 2, three elements of the framework are derived as outlined in Figure 11. It is indicated by these elements that the development and operation of smart community infrastructures should be carried out based on its overall structure beyond individual infrastructures.
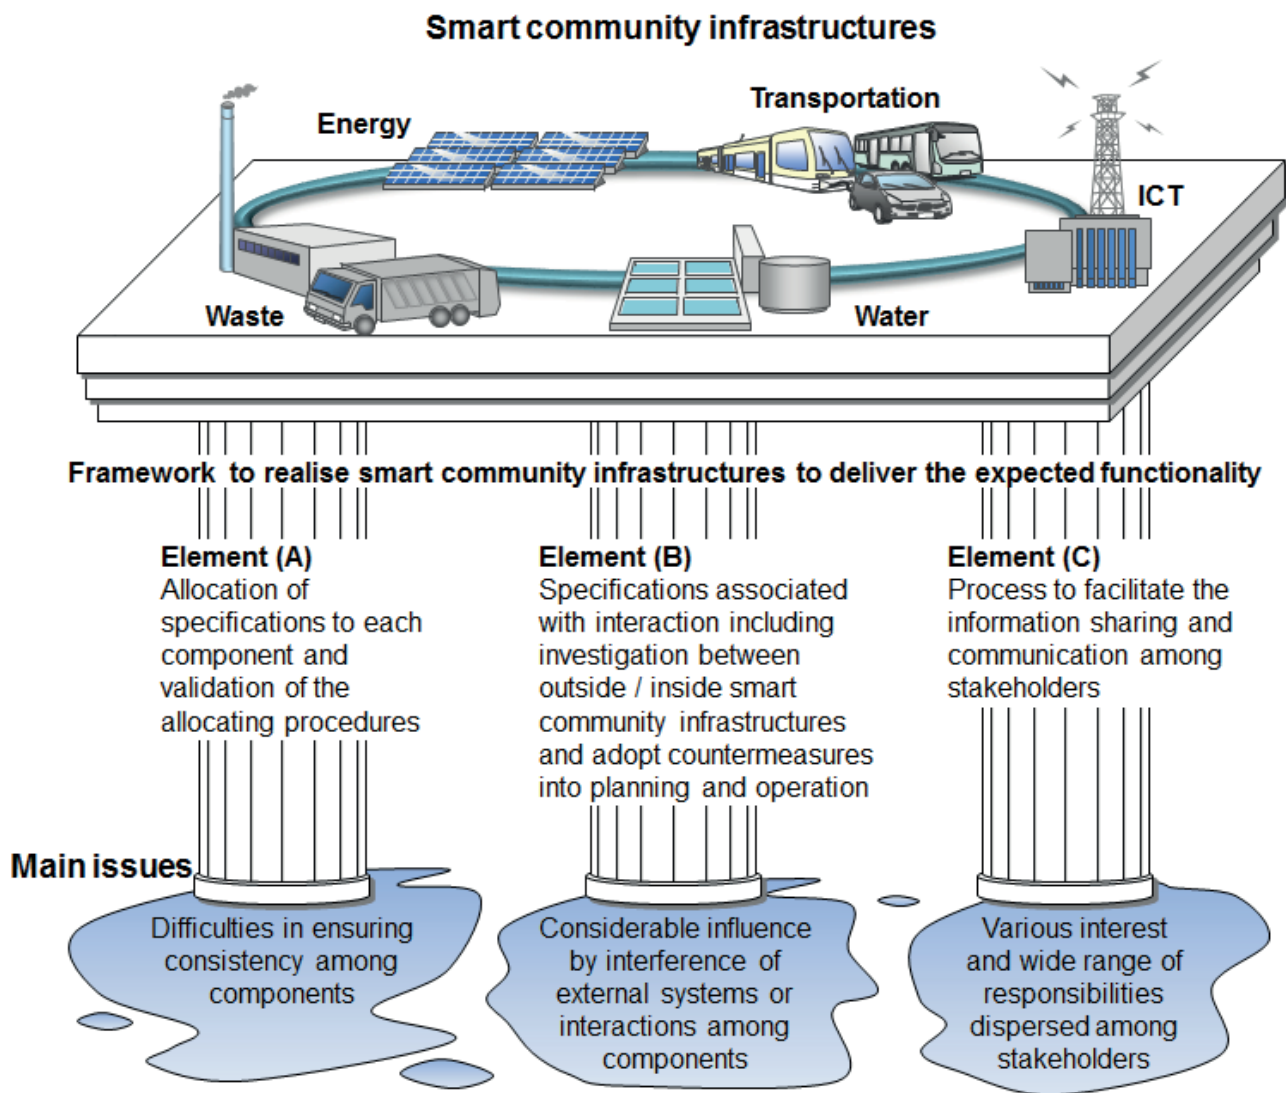

Figure 11 — Three elements of the framework

3.2 Elements of the framework

3.2.1 Element (A): Allocation of specifications to each component and validation of the allocating procedures

The following process is effective in order to ensure the consistency and the functionality of smart community infrastructures as a whole:

— Setting the requirements and needs to the entire smart community infrastructures as the starting point, functions necessary to satisfy them should be allocated from the higher level (individual infrastructures, subsystems, equipment and devices).

— This step is the most fundamental process to be carried out throughout all development phases, starting from the basic concept, master plan and design.

— In each phase of the development, adequacy of the allocated function and consistency among the allocated functions (if there is any function that interrupts other ones, etc.) should be determined.

— In each phase of the construction, accuracy in the implementation of the design should be verified through tests and analysis.

— This step should be carried out at any level adequate to test, such as at equipment level or system level as an assembly of equipment, or at the individual infrastructure level.

The above mentioned process is known as "Systems Assurance", which is a methodology for system design already used in practice for complex systems such as railway system. Especially for the railways, a set of Systems Assurance based processes has been codified in an international standard (IEC 62278 and so on), whose purpose is to ensure satisfaction of the requirements of RAMS (Reliability, Availability, Maintainability, and Safety) of the railway system and to demonstrate the conformity with the requirements.

Take "Safety" in IEC 62278, necessary functions are allocated from the system level down to the device level by setting the safety target for the entire system as the starting point. Then the level of reliability to be achieved (Safety Integrity Level: SIL) is determined for each device. In the construction phase, it is required to prove the satisfaction of SIL by each device by testing or other methods.

While SIL is a concept specifically used for the safety aspect of systems, Systems Assurance process is applied in wide variety of industries such as nuclear power plants and vehicles. Figure 12 shows the life cycle process of smart community infrastructures in terms of Systems Assurance processes.
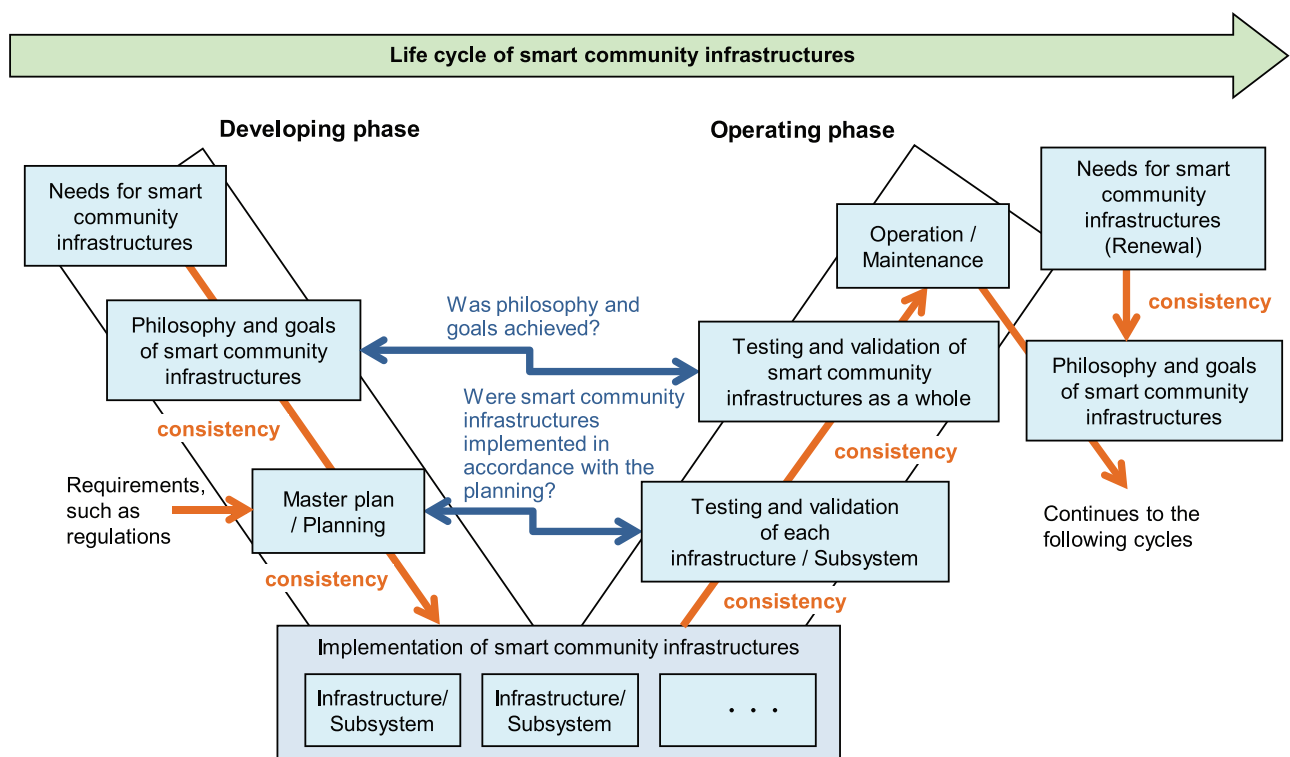

Figure 12 — Example of the process applied to development and operation of smart community infrastructures

3.2.2 Element (B): Specifications associated with interaction including investigation between outside/inside smart community infrastructures and adopt countermeasures into planning and operation

In order to mitigate risks by managing the interactions among individual infrastructures, or the interactions of the internal infrastructures with external systems (including the infrastructures out of the development scope), it is not sufficient only to consider the interactions as "the external conditions". It is also necessary to consider the changes in these conditions and risks generated from them, which

then should be accommodated in the system design (See Figure 13). To consider and accommodate such factors, the following approach can be applied:

— Identify the interactions among individual infrastructures or the interactions of the infrastructures to be developed with external systems;

— Analyse and calculate the changes expected to occur in each interaction, then to extract the risks generated from each interaction;

— Examine the countermeasures to mitigate the risks from the design and operation point of views, then to include them in the system design (including the operation design);

— Demonstrate that the countermeasures devised in the design are physically realized by testing and analysis.
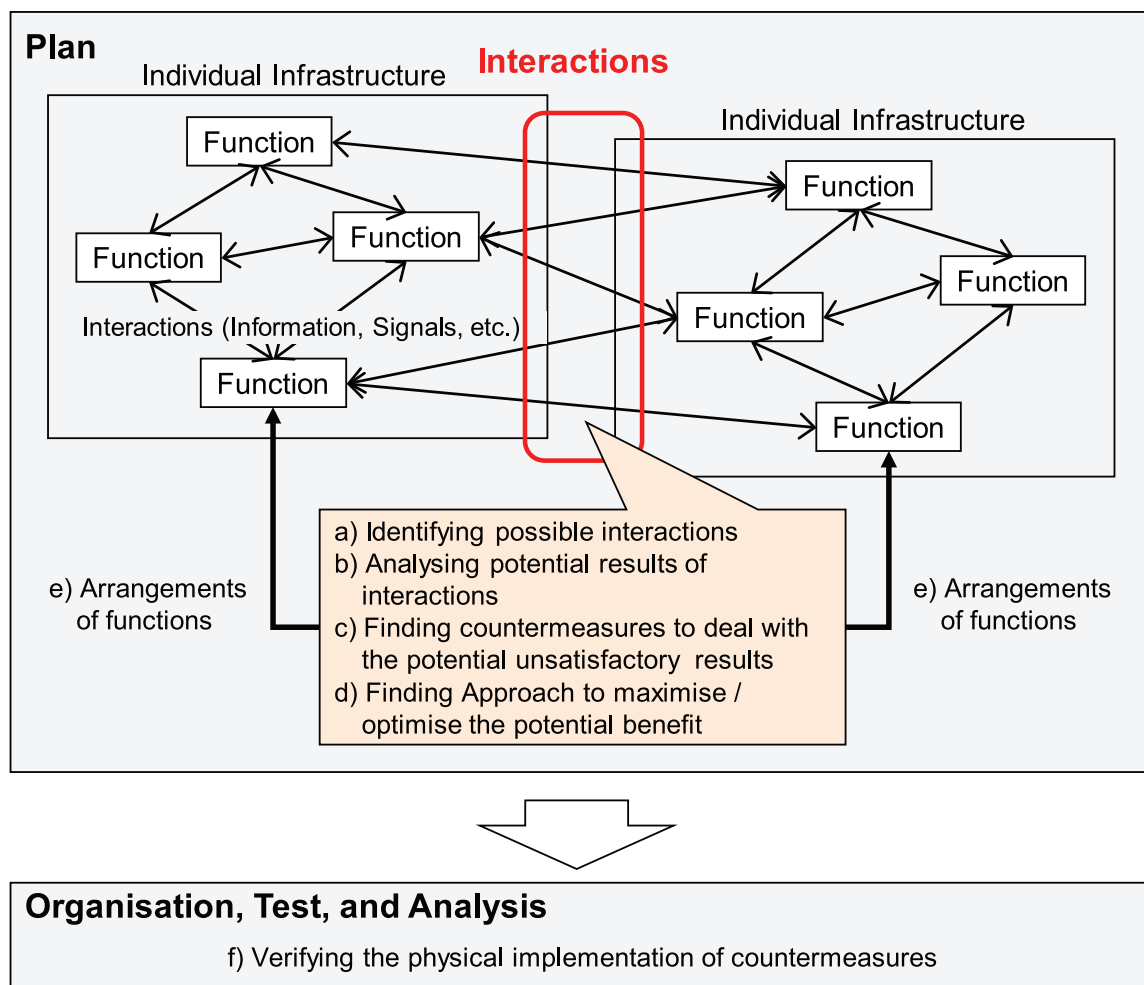

Figure 13 — Process to analyse interactions

3.2.3 Element (C): Process to facilitate the information sharing and communication among stakeholders

As shown in Figure 14, for information sharing on risks and other factors, and for consensus building, two sets of rules should be followed by each stakeholder:

— Rules to determine which information to be shared (specific items and parameters, documentation formats and guidelines, and so on);

— Rules to determine how to manage the shared information (procedures, human resource assignment, update timing/change management, and so on).
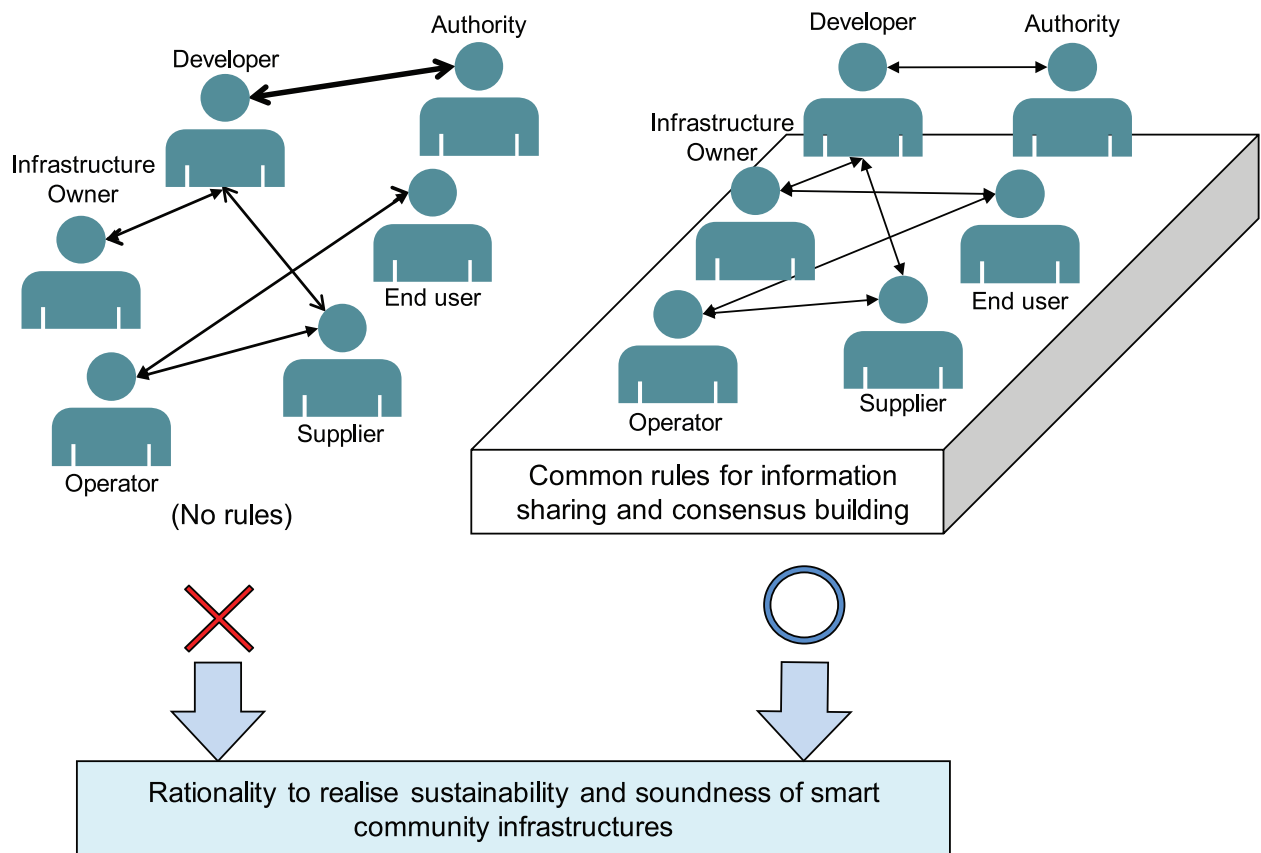

Figure 14 — Importance of common rules for information sharing and consensus building[2]

3.3 Benefits of the framework

Benefits that will be obtained in a project of developing and operating smart community infrastructures (project benefits) are shown in Table 2. The benefits are classified by the following factors:

— Stakeholders: developers, investors, operators / suppliers/authorities/end users

— Life cycle phases: project launch, basic concepts/design and development, construction/operation, redevelopment

In the classifications regarding the stakeholders, developers, investors, and operators are all concerned with the development and operation of the entire smart community infrastructures. In this sense their business overlap, and thus the similar benefits of the elements will be appreciated by all of them. Therefore they are grouped in the same category.

Business benefits to be appreciated by each stakeholder are shown in Table 3. Since the business benefits of the elements should be different depending on the life cycle phase, they are summarized by the life cycle phase.

Table 2 - Benefits that will be obtained in a project of developing and operating smart community infrastructures (1 of 3)

Stakeholders	Elements of the framework		
	Element (A): Allocation of specifications to each component and validation of the allocating procedures	Element (B): Specifications associated with interaction including investigation between outside / inside smart community infrastructures and adopt countermeasures into planning and operation	Element (C): Process to facilitate the information sharing and communication among stakeholders
Developers, Investors, Operators	**Phase1: Project launch, Basic concepts** — Functions are properly allocated to each infrastructure, so that the efficiency of the entire smart community infrastructures is optimised at the stage of basic concept design. **Phase2: Design, development** — Functions are properly allocated to each components, so that the consistency of the entire smart community infrastructures is ensured. — Effective procurement management will become possible also. — Project goes smoothly by preventing reworks due to inconsistency or mismatches among components. **Phase3: Operation, Redevelopment** — Accountability is established for conformity with requirements and needs to Infrastructures and for their realisation by adequately assembled components.	**Phase1: Project launch, Basic concepts** — By considering the interactions among infrastructures from the basic concept design phase, inefficiency due to mismatching among infrastructures can be prevented. **Phase2: Design, development** — Robust countermeasures against risks due to the interactions among components can be implemented so that the entire smart community infrastructures become consistent. **Phase3: Operation, Redevelopment** — Changes in interactions for operation can be efficiently accommodated based on the analysis from design and development phases.	**Phase1: Project launch, Basic concepts** — By receiving information necessary for solutions from stakeholders concerned in individual infrastructures, the efficiency of the entire smart community infrastructures can be improved. **Phase2: Design, development** — By making progress of the project visible through documentation and other processes, the project management becomes efficient. **Phase3: Operation, Redevelopment** — Changes in external environment and troubles in operation can be properly handled in timely manner by utilising the shared information among stakeholders.

Table 2 - Benefits that will be obtained in a project of developing and operating smart community infrastructures (2 of 3)

Stakeholders	Elements of the framework		
	Element (A): Allocation of specifications to each component and validation of the allocating procedures	Element (B): Specifications associated with interaction including investigation between outside / inside smart community infrastructures and adopt countermeasures into planning and operation	Element (C): Process to facilitate the information sharing and communication among stakeholders
Suppliers	**Phase1: Project launch, Basic concepts** — Clarification on functionality required for individual infrastructures makes system requirements specific, and therefore allows suppliers to fund and to join the project from earlier stage. **Phase2: Design, development** — Project goes smoothly by preventing reworks due to inconsistency or mismatches among components. **Phase3: Operation, Redevelopment** — Accountability is established for how much the system to provide contributes to meet requirements and needs to smart community infrastructures. — Based on clearly defined requirements to the system to provide, technical improvement, maintenance, repair etc. become possible without affecting other infrastructures in smart communities.	**Phase2: Design, development** — Clarification on the risks from interactions with other infrastructures and their components enables efficient implementation of countermeasures. **Phase3: Operation, Redevelopment** — Changes in interactions can be efficiently handled based on the analysis from design and development phases.	**Phase1: Project launch, Basic concepts** — By utilising the shared information regarding the requirements of the systems to provide, suppliers can fund and join the project from earlier stage. **Phase2: Design, development** — The shared information regarding other systems and their components enables efficient design and development. **Phase3: Operation, Redevelopment** — Changes in other infrastructures and in interactions from operation can be grasped accurately and in timely manner.

Table 2 - Benefits that will be obtained in a project of developing and operating smart community infrastructures (3 of 3)

Stakeholders	Elements of the framework		
	Element (A): Allocation of specifications to each component and validation of the allocating procedures	Element (B): Specifications associated with interaction including investigation between outside / inside smart community infrastructures and adopt countermeasures into planning and operation	Element (C): Process to facilitate the information sharing and communication among stakeholders
Authorities	**Phase2: Design, development** — Accountability of components for risks can be effectively established. **Phase3: Operation, Redevelopment** — Tracing the root cause and the responsibility becomes easier for the troubles in the operation.	**Phase2: Design, development** — Accountability for reduction in risks from interactions can be effectively established. **Phase3: Operation, Redevelopment** — Affected areas in operation troubles can be easily grasped.	**Phase1: Project launch, Basic concepts** — Authorities can share the information on risks with other stakeholders from the basic concept design phase so that necessary adjustments can be made in early stage of the project. **Phase2: Design, development** — Risks, implemented countermeasures and responsibilities can be effectively grasped. **Phase3: Operation, Redevelopment** — In case of operational troubles, necessary information can be obtained in timely manner.
End users	**Phase1: Project launch, Basic concepts** — Assurance of the conformity with requirements and needs to the entire smart community infrastructures enables decision making for purchase or investment at early stage. **Phase3: Operation, Redevelopment** — End users can choose satisfactory smart communities in which smart community infrastructures are properly and efficiently operated.	**Phase3: Operation, Redevelopment** — End users can choose a smart community which is composed of smart community infrastructures resistant to environment changes and troubles. — Environment changes and troubles inside and outside of a smart community can be grasped in timely manner.	**Phase2; Design, development** — Obtaining risk information enables decision making for purchase or investment at early stage. **Phase3; Operation, Redevelopment** — Status of smart community infrastructures is always accessible.

British Standards Institution (BSI)

BSI is the national body responsible for preparing British Standards and other standards-related publications, information and services.

BSI is incorporated by Royal Charter. British Standards and other standardization products are published by BSI Standards Limited.

About us

We bring together business, industry, government, consumers, innovators and others to shape their combined experience and expertise into standards-based solutions.

The knowledge embodied in our standards has been carefully assembled in a dependable format and refined through our open consultation process. Organizations of all sizes and across all sectors choose standards to help them achieve their goals.

Information on standards

We can provide you with the knowledge that your organization needs to succeed. Find out more about British Standards by visiting our website at bsigroup.com/standards or contacting our Customer Services team or Knowledge Centre.

Buying standards

You can buy and download PDF versions of BSI publications, including British and adopted European and international standards, through our website at bsigroup.com/shop, where hard copies can also be purchased.

If you need international and foreign standards from other Standards Development Organizations, hard copies can be ordered from our Customer Services team.

Copyright in BSI publications

All the content in BSI publications, including British Standards, is the property of and copyrighted by BSI or some person or entity that owns copyright in the information used (such as the international standardization bodies) and has formally licensed such information to BSI for commercial publication and use.

Save for the provisions below, you may not transfer, share or disseminate any portion of the standard to any other person. You may not adapt, distribute, commercially exploit, or publicly display the standard or any portion thereof in any manner whatsoever without BSI's prior written consent.

Storing and using standards

Standards purchased in soft copy format:

- A British Standard purchased in soft copy format is licensed to a sole named user for personal or internal company use only.

- The standard may be stored on more than 1 device provided that it is accessible by the sole named user only and that only 1 copy is accessed at any one time.

- A single paper copy may be printed for personal or internal company use only.

Standards purchased in hard copy format:

- A British Standard purchased in hard copy format is for personal or internal company use only.

- It may not be further reproduced – in any format – to create an additional copy. This includes scanning of the document.

If you need more than 1 copy of the document, or if you wish to share the document on an internal network, you can save money by choosing a subscription product (see 'Subscriptions').

Reproducing extracts

For permission to reproduce content from BSI publications contact the BSI Copyright & Licensing team.

Subscriptions

Our range of subscription services are designed to make using standards easier for you. For further information on our subscription products go to bsigroup.com/subscriptions.

With **British Standards Online (BSOL)** you'll have instant access to over 55,000 British and adopted European and international standards from your desktop. It's available 24/7 and is refreshed daily so you'll always be up to date.

You can keep in touch with standards developments and receive substantial discounts on the purchase price of standards, both in single copy and subscription format, by becoming a **BSI Subscribing Member**.

PLUS is an updating service exclusive to BSI Subscribing Members. You will automatically receive the latest hard copy of your standards when they're revised or replaced.

To find out more about becoming a BSI Subscribing Member and the benefits of membership, please visit bsigroup.com/shop.

With a **Multi-User Network Licence (MUNL)** you are able to host standards publications on your intranet. Licences can cover as few or as many users as you wish. With updates supplied as soon as they're available, you can be sure your documentation is current. For further information, email subscriptions@bsigroup.com.

Revisions

Our British Standards and other publications are updated by amendment or revision.

We continually improve the quality of our products and services to benefit your business. If you find an inaccuracy or ambiguity within a British Standard or other BSI publication please inform the Knowledge Centre.
